Preface to the Twelfth Edition

Although a large printing of the eleventh edition of *A Class-book of Botany* was taken in hand in 1959 the publishers had to issue seven consecutive impressions during this short period to meet the ever-increasing demand for the book. In the meantime with the gradual expansion of higher secondary schools and pre-university classes in most of the States the author felt the necessity for remodelling the current edition of the book on the basis of the new syllabuses drawn up for the Pre-University, Pre-Medical, Intermediate and Higher Secondary examinations so that the students preparing for these examinations would be benefited all the more by using this book.

With this end in view several topics have been rewritten in a simpler style, necessary additions, alterations and omissions made, and the text as a whole simplified and condensed. Unnecessary details and complications have been avoided and simple language used throughout so that the students may find the book easily comprehensible. The text has been profusely illustrated with clear sketches and photographs, and the students are well advised to refer to them frequently for easy understanding of the topics dealt with. A new part on Economic Botany (Part IX) has been added, and a set of selected questions covering the whole range of the text appended (Appendix I). The life-histories of some eminent scientists with illustrations (figs. 478-81) is also a new feature. The glossary of names of plants in eleven State languages (Appendix II) in addition to their English and Botanical equivalents is expected to be useful to a wider circle of students. The illustrations are the author's original drawings and photographs with the exception of fig. 274 which has been redrawn from *Fundamentals of Cytology* by L. W. Sharp with the kind permission of McGraw Hill Book Company, Inc. The author believes that the book, as it stands now with its manifold improvements, will meet all the needs of students and prove particularly useful to them.

Valuable suggestions have been received from Principal R. L. Nirula of Sree Nilkantheshwar College, Khandwa, Prof

R. K. Sarker of Bangabasi College, Calcutta, Prof S. Ghose of St. Xavier's College, Calcutta, Prof P. C. Das of Cotton College, Gauhati, Prof Hukamchand of Government College, Dharm-sala, Prof B. K. Gowel of Government College, Mandi, Prof R. Suryanarayanan of Government Brennen College, Tellichery, Prof V. G. Bilolikar of College of Arts and Science, Hanamkonda, and many others. The author takes this opportunity to express his sincere thanks and gratitude to all of them. Further, the addition of Kannada names of plants to the glossary (Appendix II) goes to the credit of Prof M. S. S. Rao of Basaveshvar College, Bagalkot, and the author acknowledges with pleasure and gratitude the ungrudging help rendered by Prof Rao in this direction.

Preface to the First Edition

This book, though intended primarily for the use of Intermediate and Medical students of Calcutta University and of the Dacca Board, covers somewhat wider grounds, and students of other universities, following the same or a slightly higher standard in the curricula, will find the book useful and instructive. Although the generally accepted methods of treatment have been followed, attention may be drawn to certain special features:

1. The text has been illustrated with numerous simple figures and explanatory diagrams drawn by the author himself in most cases directly from objects which are typical and easily available. The figures and diagrams have been drawn with a view to a correct and easy appreciation of them.
2. An attempt has been made to familiarize the students with the meanings of Latin and Greek prefixes and suffixes, and to trace the technical and scientific terms to their respective Latin and Greek roots. This will enable the students to master the subject of terminology more easily.
3. In many cases more than one example have been given to illustrate a particular form or feature. A large number of English and vernacular names have been introduced to suit the convenience of students. Latin names have been followed by vernacular or English equivalents, or often by both.

The author takes this opportunity of thanking Dr D. Thomson, M.A., B.Sc., Ph.D., I.E.S., Principal, Cotton College, Gauhati, for the encouragement received from him in the course of the preparation of this book. For some of the drawings the author expresses his thanks to his pupils, Madhab Chandra Das and Gour Mohan Das.

INDEX	408

INTRODUCTION

1. **Biology : botany and zoology.** The science that deals with the study of living objects goes by the general name of **biology** (*bios*, life ; *logos*, discourse or science). Since both animals and plants are living, biology includes a study of both. Biology is, therefore, divided into two branches: **botany** (*botane*, plant) which treats of plants and **zoology** (*zoon*, animal) which treats of animals.

2. **Scope of Biology.** The subject of biology deals with the study of plants and animals from many points of view. This science investigates the internal and external structures of plants and animals, their functions in regard to nutrition, growth, movements and reproduction, their adaptations to the varying conditions of the environment, their distribution in space and time, their life-history, relationship and classification, the laws involved in their evolution from lower and simpler forms to higher and more complex ones, the laws of heredity, the varied uses that plants and animals may be put to, and lastly, the different methods that can be adapted to improve them for better uses by mankind.

3. **Origin and Continuity of Life.** We do not know what life really is. It is something mysterious, and its origin is equally so. It is, however, assumed that many millions of years ago life first came into existence in water as a droplet of protoplasm (*proto*\$\delta\$, first ; *plasma*, form) from inorganic or non-living materials as a result of certain chemical and physical changes in them under certain special circumstances. Protoplasm is, therefore, the first-formed living substance, and once it came into existence its continuity has been maintained through successive generations with gradual changes of forms from simpler to more complex types of plants and animals extending over many millions of years, or, in other words, life is one continuous flow through many channels from the earliest and simplest forms to the present-day complex and diversified forms of plants and animals. Although forms of life have changed, protoplasm has remained constant in both plants and animals. Protoplasm is not formed afresh in nature, nor can it be created in the laboratory.

4. Importance of Green Plants. Green plants purify the atmosphere by absorbing carbon dioxide gas from it and releasing from their bodies (by the breaking-down of water) an almost equal volume of pure oxygen to it ; and they prepare food such as starch, the chief constituent of rice, wheat, potato, etc., from carbon dioxide obtained from the air, and water and inorganic salts obtained from the soil. Both these functions are the monopoly of green plants, and are performed by certain minute green bodies or plastids (see fig. I, called chloroplasts (*chloros*, green) of the leaf during the daytime, sunlight being the source of energy. Animals being devoid of them have no such power. It is evident, therefore, that animals including human beings are deeply indebted to plants for these basic needs, viz., oxygen for respiration and food for nutrition.

5. The Cell. Cells are the structural units of which the body of the plant or animal is composed. When the cell was first discovered by Robert Hooke in 1665 in a thin slice of bottle cork, it was regarded as a mere microscopic chamber bounded by a distinct wall—the cell-wall. Much later, however, about the year 1838-9, Schleiden—a German botanist—and Schwann—a German zoologist—discovered for the first time that a living substance, i.e. **protoplasm**, filled up the cell. A tiny spherical body, i.e. the **nucleus**, was also found lying embedded in the protoplasm. With rapid improvement of the

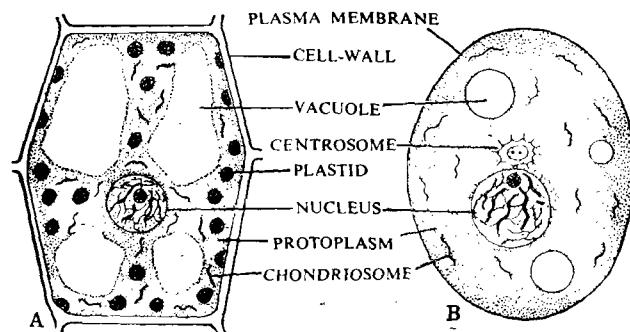

FIG. I. A plant cell and an animal cell.

microscope, attention was focused on these two bodies, and their functions soon came to be known. It was soon recognized that the protoplasm and the nucleus were the most important parts of the cell, and the cell-wall a mere by-product of the protoplasm and a structure of secondary impor-

tance. On the above basis *the cell is defined as a unit or independent mass of protoplasm with a nucleus in it, enveloped by a distinct cell-wall in the case of a plant but only a thin membrane in the case of an animal.* The whole body of the plant or the animal is made of such cells. Cells, when young, are commonly spherical or oval in shape but as they grow they assume different shapes and perform different functions.

6. **Tissue.** In pursuance of a particular function *cells similar in shape and size and having the same origin combine into a bigger unit or group called the tissue.* In the simplest organisms all the functions are performed by a single cell. But in complex forms of plants and animals with differentiated organs there is always a division of labour, i.e. distribution of functions, one group of cells performing one function and another group another function. Each such group of cells is a tissue. There are different kinds of tissues in higher plants and higher animals performing different and distinct functions. Tissues again combine and give rise to tissue systems.

7. **Protoplasm.** Protoplasm is the first-formed living substance and is a very delicate and complicated one. It is the only substance that is endowed with life and is the same in both animals and plants. All vital functions such as nutrition, growth, respiration, reproduction, etc., are performed by it. As the protoplasm dies the cell ceases to perform any of these functions. It is thus fitly described as the *physical basis of life.*

Physical Nature of Protoplasm. Protoplasm is a transparent, foamy or granular, slimy, semi-fluid substance, somewhat like the white of an egg. It is never homogeneous but contains granules of varying shapes and sizes, and it looks finely granular under the microscope. Although often semi-fluid it may be fluid or viscous. It occurs completely filling up the cavity of the young cell but in a mature cell one or more cavities, called **vacuoles**, appear in it, filled with water (see fig. 1). In its *active* state protoplasm remains saturated with water, containing 75-90% of it. With decreasing water content its vital activity diminishes and gradually comes to a standstill, as in dry seeds. Protoplasm coagulates on heating, and when killed it loses its transparency.

Protoplasm responds to the action of external stimuli such

as the prick of a needle or pin, an electric shock, application of particular chemicals, sudden variation of temperature or of light, etc. On stimulation the protoplasm contracts but expands again when the stimulating agent is removed. This response to stimuli is an inherent power of protoplasm. Protoplasm is semi-permeable in nature, i.e. it allows only certain substances and not all to enter its body. This property is, however, lost when the protoplasm is killed. Under normal conditions the protoplasm of a living cell is in a state of motion which can be seen under a microscope.

Chemical Nature of Protoplasm. Chemically protoplasm is a highly complex mixture of a variety of chemical substances of which proteins are the chief. Proteins are composed of carbon, hydrogen, oxygen and nitrogen, and sometimes also sulphur and phosphorus. The exact chemical composition of the living protoplasm cannot be determined because any attempt to analyse it kills it outright with some unknown changes in it. Besides, it undergoes continual changes and its composition is not, therefore, constant. Further, it is not possible to get the protoplasm in a pure state free from foreign bodies. Analysis of the dead protoplasm reveals a long list of elements present in it. Of these oxygen (O), carbon (C), hydrogen (H) and nitrogen (N) are most abundant. Other elements present in smaller quantities are: chlorine (Cl), sulphur (S), phosphorus (P), silicon (Si), calcium (Ca), magnesium (Mg), potassium (K), iron (Fe) and sodium (Na); still others are present in mere traces. Active protoplasm contains a high percentage of water—usually varying from 75 to 90%. Leaving out this water, the solid matter of the protoplasm contains the following: Proteins—40 - 60% ; fats—12 - 14% ; carbohydrates—12 - 14% ; and inorganic salts—5 - 7%.

8. Characteristics of Living Objects. Life is something mysterious and we are not in a position to define it. All living objects have, however, certain characteristics by which they can be distinguished from the non-living. These are as follows:

(i) **Life-cycle.** All living objects follow a definite life-cycle of birth, growth, reproduction, old age and death. The animal or the plant is born, and gradually, it grows into its characteristic form and size. In due course it reproduces to maintain the continuity of the species and also to multiply in number. Ultimately the organism attains old age and dies.

(2) **Protoplasm.** Life cannot exist without protoplasm. It is the actual living substance in both plants and animals, and it is, as Huxley defined it, the physical basis of life. It performs all the vital functions ; it shows various kinds of movement and is sensitive to all kinds of stimuli such as light, temperature, chemical substances, electric shock, etc. Protoplasm is a very delicate and complicated substance.

(3) **Cellular Structure.** The whole body of the plant or the animal is composed of cells. A cell is a unit mass of protoplasm with a nucleus in it, surrounded by a distinct cell-wall in the case of a plant and only a thin delicate membrane in the case of an animal (see fig. 1). The cellular structure, as described above, is the characteristic feature of every living organism.

(4) **Respiration.** Respiration is a sign of life. All living beings—plants and animals—respire continuously day and night, and for this process they take in *oxygen gas* from the atmosphere and give out an almost equal volume of *carbon dioxide gas*. By this process the energy stored up in the food and other materials is released and made use of by the protoplasm for its manifold activities.

(5) **Reproduction.** Living beings—animals and plants—possess the power of reproduction, i.e. of giving rise to new young ones like themselves. Non-living objects have no such power. They may mechanically break down into a number of irregular parts ; but living objects reproduce according to certain principles.

(6) **Metabolism.** Metabolism is a phenomenon of life. It includes both constructive and destructive changes that are constantly going on in the living body. Constructive changes lead to the formation of food substances and the construction of protoplasm, while destructive changes result in their breaking down, ending in the formation of a variety of chemical substances.

(7) **Nutrition.** A living organism requires to be supplied with food. Food furnishes the necessary materials for nutrition and growth, and is a source of energy. Food materials nourishing the plant body or the animal body are much the same in both.

(8) **Growth.** All living objects grow. Some non-living bodies may also grow, as does a crystal. But there is difference in the mode of growth between the two. The growth of the non-

living objects is external, i.e. new particles are deposited on the external surface of their body from outside and as a result they grow ; while in living objects, the growth is internal, i.e. it proceeds from within, new particles being secreted by the protoplasm in the interior of their body. Further, in living bodies the growth is the result of a series of complicated processes, both constructive and destructive.

(9) **Movement.** Movements are commonly regarded as a sign of life. Movements in most plants are, however, restricted, as they are fixed to the ground : while most animals move freely. Moving plants and fixed animals are not, however, uncommon among the lower organisms. Movements in plants and animals may be *spontaneous* or *induced*.

(a) **Spontaneous movement** is the movement of an organism or of an organ of a plant or an animal of *its own accord*, i.e. without any external influence. This kind of movement is regarded as a characteristic sign of life. Spontaneous movement is evident in animals with the development of organs of locomotion ; while in plants it is exhibited by many unicellular and filamentous algae. Among the 'flowering' plants the best example of spontaneous movement is exhibited by Indian telegraph plant (*B. BAN-CHANDAL* ; *H. BAN-CHAL*—see fig. 351). Besides, the movements of protoplasm (see figs. 250-1) are distinctly visible under the microscope.

(b) **Induced movement** or **irritability**, on the other hand, is the movement of living organisms or of their organs in response to external stimuli. Protoplasm is sensitive to a variety of external stimuli, and when a particular stimulus is applied the reaction is usually in the form of a movement. Thus when an animal burns itself it immediately moves away from the source of heat. A pin prick or electric shock produces a similar effect. Seedlings grown in a closed box with an open window on one side (see fig. 352) grow and bend towards the window, i.e. towards the source of light. Leaflets of sensitive plant (*B. LAJJABATI-LATA* ; *H. LAJWANTI*—see fig. 357) and sensitive wood-sorrel (*B. BAN-NARANCA*—see fig. 356) close up when touched. The tentacles of sundew (see fig. 339), a carnivorous plant, bend over the insect from all sides and entrap it, when it falls on the leaf. Leaves of many plants show 'sleep movement', closing up in the evening and opening again in the morning. No such effect is produced in the case of non-living

objects like a log of wood or a bar of metal. Irritability is, however, more pronounced in animals than in plants.

9. Differences between the Living and the Non-living. It is very difficult to trace the absolute differences between the living and the non-living. Certain points may, however, be cited by way of general differences between the two.

Living

Protoplasm. All living objects contain protoplasm which is the physical basis of life and performs all the vital functions.

(2) **Life-cycle.** All living objects follow a definite life-cycle comprising birth, growth, reproduction, old age and death.

(3) **Cellular structure.** A living body is composed of regular cells and is well organized in form and size, both externally and internally.

(4) **Respiration.** This is a complex vital process, resulting in breakdown of food with the release of CO_2 and considerable energy at all times and at all temperatures.

(5) **Metabolism.** Metabolic changes (constructive and destructive) are a characteristic sign of life.

(6) **Nutrition.** Nutrition through food is a regular feature in all living organisms.

(7) **Reproduction.** All living objects reproduce periodically by one or more methods for continuation of the species.

(8) **Growth.** Growth in living objects is internal, i.e. it proceeds from within the cell as a result of metabolic changes.

(9) **Movement.** Spontaneous movement is a characteristic sign of life —either movement of protoplasm or of an entire organism or of some of the organs.

Non-living

(1) Non-living objects are conspicuous by its absence and, therefore, no vital activity is possible in them.

(2) Non-living objects have no life-cycle. They may exist in their original state, may disintegrate or may change chemically or otherwise.

(3) A non-living body is not cellular nor is it organized (except crystals). It is only made of a mass of particles of one or more kinds.

(4) Non-living objects do not respire. But burning of coal or firewood at a high temperature only releases CO_2 and some energy. The chemical mechanism, however, is altogether different.

(5) No such changes are found in non-living objects. Chemical change, if any, in them is uncertain and irregular.

(6) Non-living objects require no food. Natural wear and tear cannot be made good by a supply of food.

(7) Non-living objects cannot reproduce their own kind. They may, however, break down mechanically into some irregular pieces.

(8) Growth, if any, in non-living objects is external, i.e. it proceeds on the external surface only; no metabolic change is involved in this process.

(9) Such a movement is never exhibited by non-living objects. The latter, however, can be made to move by some external forces, natural or mechanical.

10. **Distinctions between Plants and Animals.** Higher plants and higher animals are readily distinguished from one another by their possession of distinctive organs in both cases for the discharge of definite functions ; but it is very difficult to make a distinction between unicellular plants and animals. The distinguishing features in general are, however, as follows :

(1) **The Cell-wall and Cellulose.** While both plants and animals are cellular in composition, a plant cell is surrounded by a distinct cell-wall made of cellulose or any modification of it. Pure cellulose is not, however, found in fungi. The cell-wall and cellulose are always absent in an animal cell. The latter is surrounded by a thin cytoplasmic membrane called the plasma membrane.

(2) **Chlorophyll.** Chlorophyll, the green colouring matter of leaves and tender shoots, is highly characteristic of plants with the exception of fungi and total parasites. Chlorophyll is contained in special protoplasmic bodies, called plastids (see fig. 1), which often occur in large numbers in a cell. Chlorophyll and plastids are conspicuous by their absence in animal cells. Some animals may, however, turn green in colour by feeding upon green parts of plants.

(3) **Utilization of Carbon Dioxide.** Plants possess the power of utilizing the carbon dioxide of the atmosphere. It is only the green cells that have got this power. Thus during the daytime the green cells of the leaf absorb carbon dioxide from the surrounding air, manufacture sugar, starch, etc., and give out an almost equal volume of oxygen (by the breakdown of water in the process). Animals do not possess this power of utilizing carbon dioxide or of manufacturing food.

(4) **Food.** Green plants absorb raw food materials from outside—water and inorganic salts from the soil and carbon dioxide from the air—and prepare organic food substances out of them, primarily in the leaf, with the help of chlorophyll in the presence of sunlight. Animals being devoid of chlorophyll have no power of manufacturing their own food. They have solely to depend directly or indirectly on plants for this primary need. It is also to be noted that plants take in food in solution only, whereas animals can ingest solid food particles.

(5) **Growth.** The regions of growth are localized in plants, lying primarily at the extremities—root-apex and stem-apex—and also in the interior, i.e. growth is both apical and intercalary ; while in animals growth is not localized to any definite

region, i.e. all parts grow simultaneously. Moreover, in plants growth proceeds until death ; while in animals growth ceases long before death.

(6) **Movements.** Plants grow fixed to the ground or attached to some support, and as such they cannot bodily move from one place to another, except some lower types of plants ; while animals move freely in search of food and shelter, and also when attacked ; some animals, of course, grow attached to some object, and thus cannot freely move.

(7) **Vacuole and Centrosome.** The vacuole is a common feature of a mature plant cell and is often so much enlarged as to occupy the major portion of it (see fig. I). In the animal cell the vacuole is somewhat rare and, if present, is small in size. The centrosome, a protoplasmic body, lying close to the nucleus, is a regular feature of the animal cell and is associated with the division of the nucleus. It is very rare in the plant cell, occurring occasionally only in some lower plants.

11. **Binomial Nomenclature.** In classifying plants and animals Linnaeus, a Swedish naturalist, first introduced a system of designating each and every species of plant or animal with a binomial consisting of two parts—the first refers to the genus and the second to the species. A species is defined as a group of individuals—plants or animals—resembling one another in almost all respects, differing only in minor details. A genus is a group of closely allied species. This system of naming a plant or animal with two parts (genus and species) is called binomial nomenclature. Since the popular name of a species varies from country to country this system of naming plants and animals has been universally accepted as the correct scientific system. Thus mango is designated as *Mangifera indica*, pea as *Pisum sativum*, onion as *Allium cepa*, garlic as *Allium sativum*, etc.

12. **Chief Groups of Plants.** There are two main divisions of the plant kingdom, viz., **cryptogams** and **phanerogams**. Cryptogams are lower plants which never bear flowers or seeds, while phanerogams are higher plants which always bear flowers and seeds. So cryptogams are regarded as ‘flowerless’ or ‘seedless’ plants, and phanerogams as ‘flowering’ or ‘seed-bearing’ plants.

A. Cryptogams. The main groups of cryptogams from the lower types to the higher are the following :

(1) **Thallophyta.** Thallophyta are lower cryptogams in which the plant body is not differentiated into the root, stem and leaf. Such an undifferentiated plant body is called a thallus and the thallus-bearing plants are called Thallophyta. The following are the chief groups of Thallophyta : (a) **Algae** (sing.

alga) are commonly green Thallophyta containing chlorophyll although this colour may be masked by other colouring matters. They mostly grow in water and are of various forms

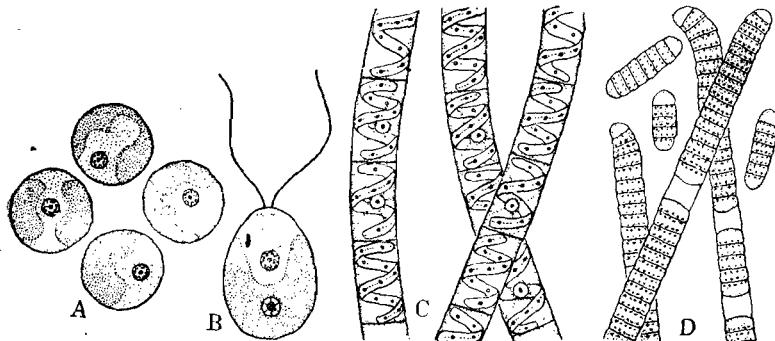

FIG. II. Forms of Algae. A, *Protococcus*—unicellular and green; B, *Chlamydomonas*—unicellular, green, ciliate and motile; C, *Spirogyra*—filamentous and green; and D, *Oscillatoria*—filamentous and blue-green.

(fig. II). (b) **Bacteria** (sing. bacterium) are the smallest known organisms, not visible to the naked eye. They are unicellular, non-green, usually spherical or rod-like (fig. IIIA). They occur almost everywhere, and are parasites (see p. 7) or sapro-

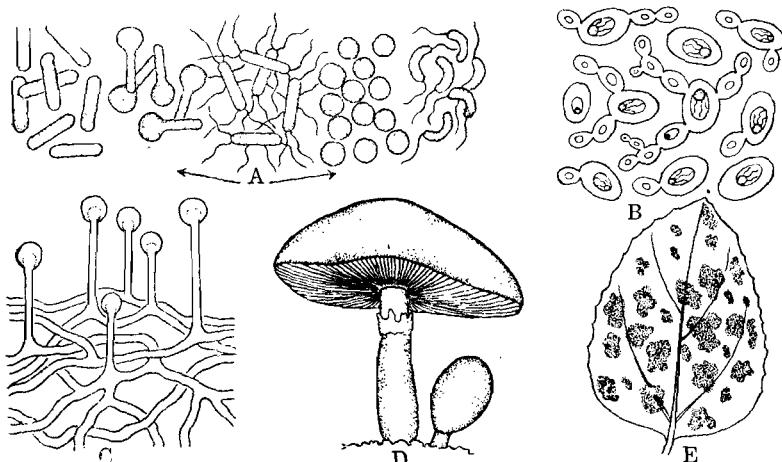

FIG. III. Forms of Bacteria and Fungi. A, bacteria—four common types; B, yeast—a unicellular fungus (mostly budding); C, mould—a filamentous fungus; D, mushroom—a fleshy fungus; and E, a parasitic fungus on a leaf.

phytes (see p. 9). (c) **Fungi** (sing. fungus) are non-green thallophytes containing no chlorophyll. They grow mostly on land

either as parasites (see p. 7) or as saprophytes (see p. 9). Like algae they may be of various forms. Common examples of fungi are mould, mushroom, toadstool, puff-ball, etc. (fig. III B-E).

(2) **Bryophyta** are a group of higher cryptograms in which the plant body may be thalloid (primitive forms) or leafy (advanced forms). They develop some root-like structures, called rhizoids, but no true roots, and the conducting tissue is very simple and primitive. They grow on old damp walls, on moist ground and on bark of trees forming a sort of beauti-

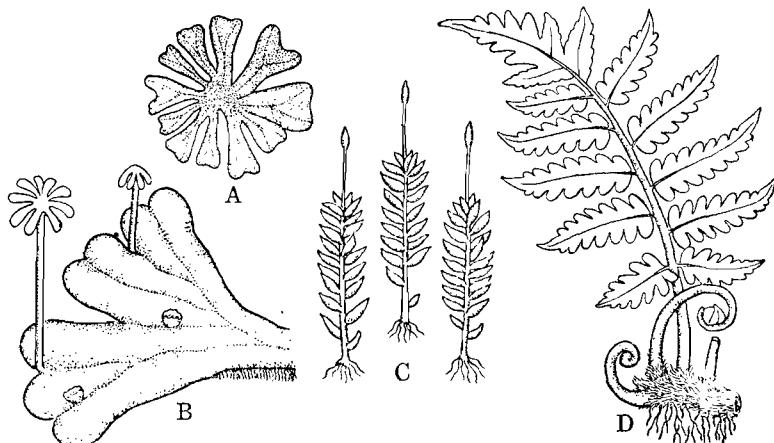

FIG. IV. Forms of Bryophyta and Pteridophyta. A, *Riccia* and B, *Marchantia*—two thalloid bryophytes; C, moss—a leafy bryophyte; D, fern—a pteridophyte.

ful, green carpet and are more complicated and mode advanced than the Thallophyta. There are two groups of Bryophyta: (a) **liverworts** or thalloid Bryophyta, e.g. *Riccia* (fig. IV A) and *Marchantia* (fig. IV B) and (b) **mosses** or leafy Bryophyta, e.g. true mosses (fig. IV C).

(3) **Pteridophyta** are the highest group of cryptogams in which the plant body is differentiated into an underground horizontal stem (rhizome) or an erect stem, well-developed green leaves and true roots. The plant body is more complicated with development of conducting and mechanical tissues. Pteridophyta are more advanced than Bryophyta. They bear spores on their leaves by which they reproduce and multiply. Ferns (see fig. IV D) and relatives are the common groups.

B. Phanerogams or Spermatophytes. These are 'flowering' or 'seed-bearing' plants. They are the most advanced types of plants with the reproductive shoot modified into a flower (simple or complex), and are divided into two main groups: gymnosperms and angiosperms.

(1) **Gymnosperms** (*gymnos*, naked; *sperma*, seed) are naked-seeded plants, i.e. those in which the seeds are not enclosed in the fruit. They may be regarded as lower 'flowering' plants in which the flowers are unisexual (either male or female), simple in construction and primitive in nature. There are two main groups of gymnosperms: (a) cycads and (b) conifers.

(2) **Angiosperms** (*angeion*, case) are closed-seeded plants i.e. those in which the seeds are enclosed in the fruit. They may be regarded as higher 'flowering' plants in which the flowers are more complicated in construction and more advanced. Angiosperms are the highest forms of plants. There are two big groups of angiosperms: (a) **dicotyledons** are the bigger group of angiosperms in which the embryo of the seed bears *two* cotyledons, and the flower commonly bears *five* petals or a multiple of this number; other characteristics are *tap* root in the root system and *reticulate* (net-like) venation in the leaves; (b) **monocotyledons** are the smaller group of angiosperms in which the embryo of the seed bears only *one* cotyledon, and the flower commonly bears *three* petals or a multiple of this number; other characteristics are *fibrous* roots in the root system and *parallel* venation in the leaves. [For further details see chapter 1 in part VII.]

Altogether about 342,400 species of plants are on record: algae—20,000; fungi—90,000; mosses and relatives—22,700; ferns and relatives—10,000; gymnosperms—700; and angiosperms—199,000 (dicotyledons—159,000 and monocotyledons—40,000).

13. Branches of Botany. Botany, like every other science, may be studied from two aspects—the *pure* and the *applied* or *economic*. Pure botany deals with the study of plants as a part of nature, and applied botany as it is applied to the well-being of mankind. The following are the main branches:

(1) **Morphology** (*morphe*, form; *logos*, discourse or science). This deals with the study of forms and features of different plant organs such as roots, stems, leaves, flowers, seeds and

fruits. It also includes a study of the development of the embryo.

(2) **Histology** (*histos*, a cobweb). The study of detailed structure of tissues making up the different organs of plants, as revealed by the microscope, is called **histology**. The study of gross internal structure of plant organs by the technique of section-cutting is called **anatomy** (*ana*, asunder; *temnein*, to cut). **Cytology** (*kytos*, cell) dealing with the cell-structure with special reference to the behaviour of the nucleus is a newly established branch of histology.

(3) **Physiology** (*physis*, nature of life). This deals with the various functions that the plants perform. Functions may be *vital* or *mechanical*; vital functions are performed by the living matter, i.e. the protoplasm, and the mechanical functions by certain dead tissues without the intervention of the protoplasm; as, for example, bark and cork protect the plant body, and certain hard tissues strengthen it. It is to be noted that structure and function are correlated, i.e. a particular structure develops in response to a particular function.

(4) **Ecology** (*oikos*, house). This deals with the relationship that exists between individual plants or plant communities and the surrounding conditions in which they live.

(5) **Taxonomy** or **Systematic Botany** (*taxis*, arrangement). This deals with the description and identification of plants, and their classification into various natural groups according to the resemblances and differences in their morphological characteristics.

(6) **Organic Evolution.** This deals with the sequence of descent of more complex, more recent and more advanced types of plants and animals from the simpler, earlier and more primitive types through successive stages in different periods of the earth.

(7) **Genetics.** This deals with the facts and laws of inheritance (variation and heredity) of characters from one generation to another.

(8) **Economic Botany.** This deals with the various uses of plants and their products, and includes methods for their improvement for better utilization by mankind.

PART I MORPHOLOGY

CHAPTER I *Diversity of Plant Life*

There are not only immense numbers of plants but they also show diversities in various directions—habitat, habit, forms and types, duration of life, mode of nutrition, etc. Many of them have also developed special (modified) organs for the discharge of special functions. Diversity is a special feature of the biological kingdom.

Habitat. The habitat is the natural home of a plant. Each habitat has its own factors, viz. a particular type of climate (rainfall, heat, wind, and light) and a particular type of soil (soil-water, its physical and chemical nature), and it has its own characteristic flora. Thus certain plants grow in the fresh water of ponds, lakes and rivers, forming what is called the aquatic flora, e.g. water lily, lotus, bladderwort, duckweed, water lettuce, *Vallisneria*, *Hydrilla*, etc. Close to a pool of water a group of moisture-loving plants are seen to grow, e.g. many grasses, aroids, mosses and ferns. In the saline water of salt lakes and seas an altogether different type of vegetation is seen. Life, however, is harder on land with varying climatic conditions and with different types of soils. In very dry regions or deserts cacti and similar plants form the dominant flora. In dry fields in winter certain weeds make their appearance, while in the same fields during the rains another set of weeds appears. In places with heavy rainfall evergreen forests grow up, while in places with moderate or low rainfall deciduous forests are seen. Then again at high altitudes certain other types of plants are found, e.g. oak, birch, pine, deodar, fir, etc. Still higher up, as in the Himalayas, certain types of stunted shrubs and small herbs only grow. It is thus evident that particular habitats suit particular types of plants.

Habits of Plants. The nature of the stem, the height of the plant, its duration and mode of life determine the habit of a plant. In habit plants show considerable diversities. Commonly the following terms are used to indicate the general habits of plants.

(1) **Herbs** are small plants with a soft stem. They may vary from a few millimetres to a metre or so in height, e.g. duckweed, mustard, radish, sunflower, ginger, *Canna*, etc. (2) **Shrubs** are medium-sized plants with a hard and woody stem, often much-branched and bushy, e.g. China rose, garden croton, night jasmine, *Duranta*, etc. (3) **Trees** are tall plants with a clear, hard and woody stem, e.g. mango, jack, *Casuarina* (B. & H. JHAU) etc. While most shrubs and trees are profusely branched, most palms, although very tall and erect, sometimes 46m. in height, are unbranched. Some trees take a conical or pyramidal shape, e.g. *Casuarina*; others become dome-shaped, e.g. banyan. Timber trees generally attain a considerable height. Thus SAL (*Shorea*) and teak (*Tectona*) attain a height of 30m., while trees like GARJAN (wood-oil tree) may be as tall as 46m. Gigantic trees like *Eucalyptus*, redwood and mammoth tree may be as high as 90m. or even more. Some of the climbers like rattan cane may be 150-180m. or even longer. Some trees are very thick, e.g. the baobab tree attains a girth of about 9m., the mammoth tree 11m., and dragon plant sometimes 14m. On the other hand plants with a soft stem cannot stand erect. Some of them (the **creepers**) only creep on the ground, e.g. wood-sorrel; some (the **climbers**) climb neighbouring objects by means of special devices (see p. 3). Others (the **twiners**) bodily twine round some support, e.g. country bean, railway creeper, Rangoon creeper, *Clitoria* (B. APARAJITA), etc. Still others (the **lianes**; see p. 6) climb large trees and reach their tops.

Forms and Types of Plants. There is a considerable diversity of plants ranging from the simplest to the most complicated and gigantic ones. Some plants are tall, or very tall, some medium-sized, some small and some so small that they are invisible to the naked eye. Among those known to us bacteria are the smallest; they are unicellular and only imperfectly seen even under a powerful microscope (see fig. IIIA). Among algae (which include pond-scum and sea-weeds) there are gradations of forms; some are unicellular, e.g. *Protococcus* (see fig. IIA), while the majority are multicellular (many-celled); the latter may be filamentous, e.g. *Spirogyra* and *Oscillatoria* (see fig. IIC-D) or massive, e.g. many sea-weeds. Similarly fungi may be unicellular, e.g. yeast (see fig. IIIB) or multicellular; the latter may be filamentous, e.g. mould or *Mucor* (see fig. IIIC), or massive e.g. mushroom or *Agaricus* (see fig. IID). Some plants are thalloid lying flat on the ground, e.g. *Riccia* and *Marchantia* (see fig. IVA-B). Mosses are short erect plants, with small green leaves but no true roots (see fig. IVC). Ferns have already become complex in structure with well-developed leaves, a stem and true roots (see fig. IVD). Flowering plants, however, show the highest degree of complexity in structure and forms varying from a few millimetres to a hundred metres or so. The latter are really gigantic trees, as stated above.

Duration of Life. The life of an individual plant is always limited in duration. Herbs have a short span of life. Those herbs that live for a few months or at most a year are said to be (1) **annuals**, e.g. rice, wheat, maize, mustard, potato, pea, etc. They grow and produce flowers and fruits within this period and then die off. Some herbs may live for two years ; such plants are said to be (2) **biennials**. They attain their full vegetative growth in the first year and produce flowers and fruits only in the second year after which they die off, e.g. cabbage, beet, carrot, turnip, etc. (in a tropical climate these vegetables, however, behave like annuals). Some herbs continue to grow from year to year with a new lease of active life for a few months only ; the aerial parts of such plants die down every year after flowering or in winter, and a fresh life begins after a few showers of rain when the underground stem puts forth new leaves. Such plants are said to be (3) **perennials**, e.g. *Canna*, ginger, KACHU (taro), onion, tuberose, etc. Shrubs generally live for a few years. Trees, however, have the greatest longevity. SAL (*Shorea*), teak, and some palms, live for 100–150 years; *Eucalyptus* for 300 years; redwood and the mammoth tree of America for 1,000–1,500 years; some conifers (pine-like trees) have a life-span of 2,500 years; some of the dragon plants (*Dracaena*) are remarkable for their longevity and their age in some cases has been estimated to be 6,000 years.

Climbers. Climbers have developed special organs of attachment by which they cling to neighbouring objects for the support of their body and for aid in climbing. Climbers may be of the following kinds.

(1) **Rootlet Climbers.** These are plants which climb by means of small adventitious roots given off from their inner side or from their nodes as they come in contact with a supporting plant or any suitable object. Such roots either form small adhesive discs or claws which act as *holdfasts* or they secrete a sticky juice which dries up, fixing the climbers to their support. Examples may be seen in betel (see fig. 56A), long pepper, ivy, Indian ivy (fig. 1), *Pothos*, etc.

(2) **Hook Climbers.** The flower-stalk of *Artabotrys* (B. & H. KANTALI-CHAMPA) produces a curved hook (fig. 4), which helps the plant to climb. Often **prickles** and **thorns** are curved and hooked in certain plants. Thus in cane (fig. 5) a long slender

axis beset with numerous sharp and curved hooks is produced

from the leaf-sheath in addition to numerous prickles on it. Climbing rose (fig. 6) is provided with numerous curved prickles for the purpose of climbing (and also for self-defence). Glory of the garden (fig. 2) and *Uncaria* (fig. 3), both large climbing shrubs, produce curved hooks (thorns) which are used as organs of support for facility of climbing.

(3) Tendril Climbers.

These are plants which produce slender, leafless, spirally-coiled structures,

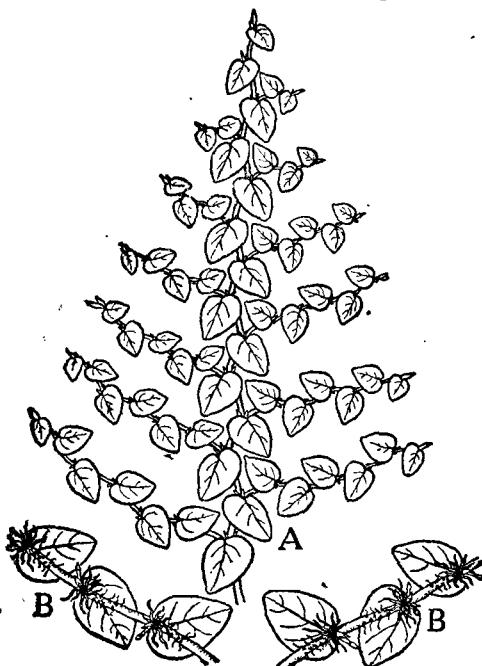

FIG. 1. Indian ivy—a rootlet climber; A, upper side; B, lower side.

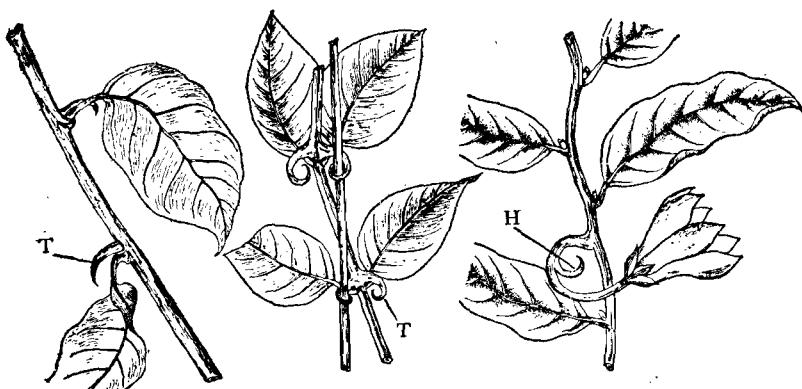

FIG. 2

FIG. 3

FIG. 4

Hook and Thorn Climbers. FIG. 2. Glory of the garden; T, thorn.
FIG. 3. *Uncaria*; T, hooked thorn. FIG. 4. *Artabotrys*; H, hook.

known as **tendrils**, and climb objects with the help of them; tendrils twine themselves round some support, and help the

plants to support their weight and climb easily. Tendrils may

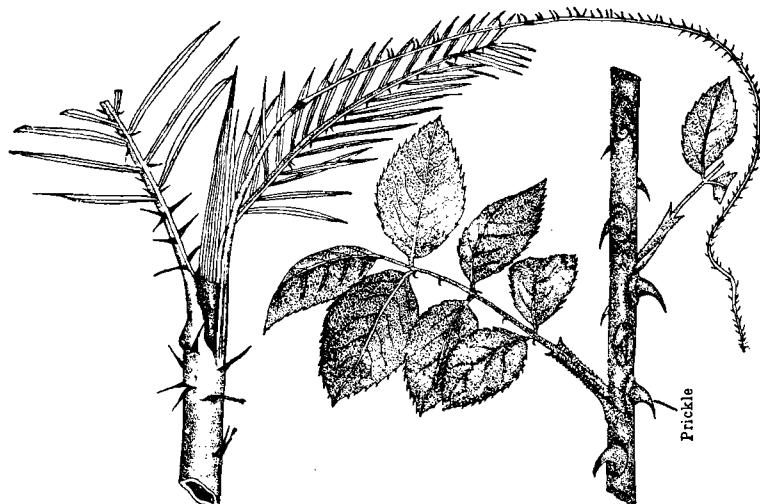

FIG. 5

FIG. 6

be modifications of the stem, as in passion-flower (fig. 7), vine,

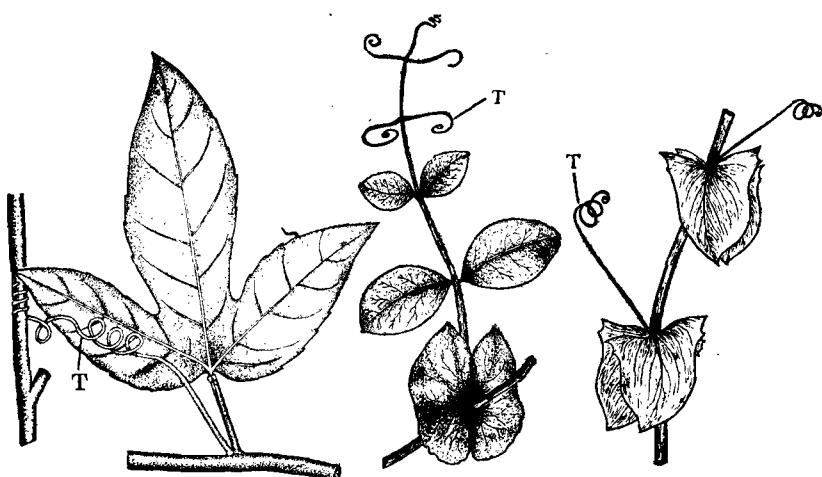

FIG. 7

FIG. 9. Wild pea (*Lathyrus*). T, tendril.

FIG. 8

FIG. 9

etc., or of leaves, as in pea (fig. 8), wild pea (fig. 9), etc., or of stipules, as in *Smilax* (see fig. 88).

(4) **Leaf Climbers.** In some plants part of the leaf is sensitive to contact with a foreign body. It acts like a tendril and helps the plant to climb. Thus the slender petiole of *Clematis* (fig. 10) twines like a tendril round a support and helps the plant to

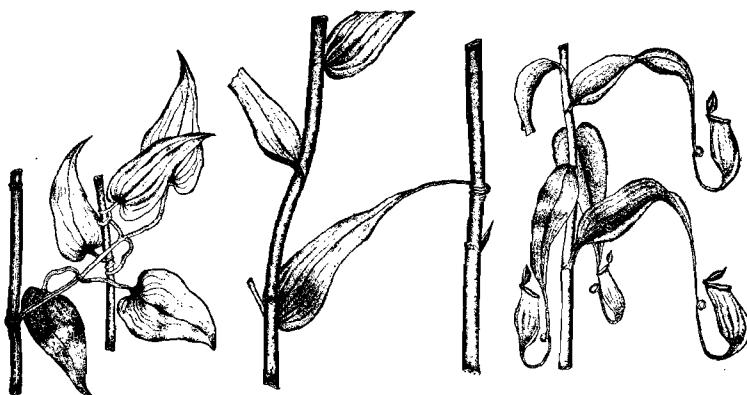

FIG. 10

FIG. 11

FIG. 12

Leaf Climbers. FIG. 10. *Clematis*. FIG. 11. Glory lily (*Gloriosa*).
FIG. 12. Pitcher plant (*Nepenthes*; see also FIGS. 120-1).

climb. In glory lily (fig. 11) the prolonged leaf-apex coils round a support like a tendril. The long stiff stalk of the pitcher of pitcher plant (fig. 12) also acts as a tendril supporting the pitcher.

Lianes. These are very thick and woody, perennial climbers, commonly met with in forests. They twine themselves round tall trees in search of sunlight, and ultimately reach their top. There they get plenty of sunlight and produce a canopy of foliage. Common examples are *Hiptage* (B. MADHABILATA ; H. MADHU-LATA), camel's foot climber (*Bauhinia vahlii* ; B. LATA-KANCHAN ; H. CHAMBULI—see fig. 240), cowage (*Mucuna* ; B. ALKUSHIR ; H. KAWANCH) and some species of fig (*Ficus*).

Special Types of Plants. Depending on the mode of nutrition plants may be divided into the following special types. All green plants prepare their own organic food, particularly carbohydrates, mostly in their leaves, from the raw or inorganic materials absorbed from the soil and the air, and nourish themselves with their own food; such plants are said to be **autophytes** or autotrophic plants (*auto*, self ; *phyton*, plant ; *trophe*, food) or self-nourishing. Non-green plants on the other hand cannot prepare their own carbohydrate food and thus they draw it (together with other kinds of food) from different sources, i.e. their modes of nutrition are different; such plants

are said to be *heterophytes* or heterotrophic plants (*heteros*, different) and they are either parasites or saprophytes. There are other types of plants whose mode of nutrition is somewhat peculiar. All such types of plants are as follows.

(1) **Parasites.** Plants that grow upon other living plants (or on animals) and absorb necessary food materials, wholly or partially, from them are called parasites. Among the 'flowering' plants there are different degrees of parasitism. Some are total parasites and others are partial parasites. Total parasites are never green in colour as they absorb all their food from the host plant, e.g. dodder (B. SWARNALATA ; H. AKASHBEL—fig.

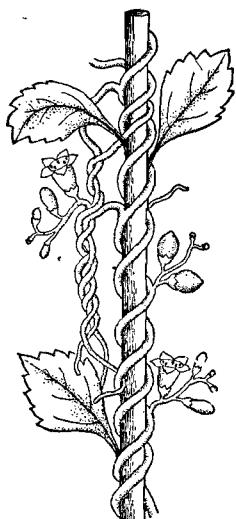

FIG. 13

FIG. 13. Dodder (*Cuscuta*)—a total stem parasite. FIG. 14. A section through dodder (and the host plant) showing the sucking root (haustorium).

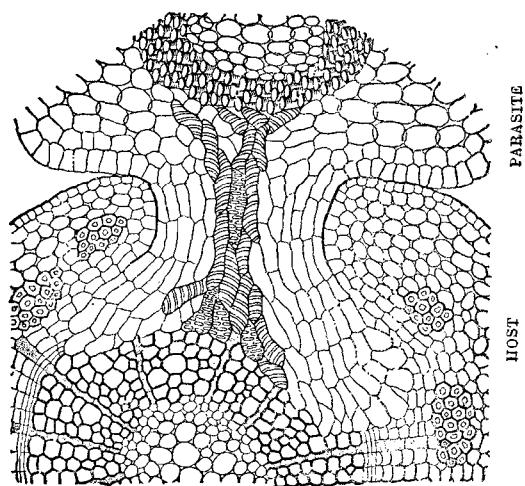

FIG. 14

13). Partial parasites on the other hand are green in colour and manufacture their food, partially at least; so they do not entirely depend on the host plant, e.g. mistletoe (B. BANDA ; H. BHANGRA—fig. 17). It is further to be noted that parasites may be attached to the stem and branches or to the root of the host plant. Accordingly they are said to be stem-parasites, e.g. dodder and mistletoe, or root-parasites, e.g. broomrape (B. BANIA-BAU ; H. SARSON-BANDA—fig. 15) and *Balanophora* (fig. 16). To absorb food from the host plant a parasite produces certain special roots, called *sucking roots* or *haustoria* (fig. 14) which

penetrate into the food-containing tissue of the host plant, secrete necessary digestive agents and finally absorb the soluble

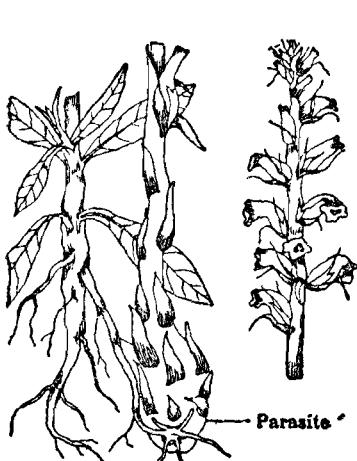

FIG. 15

FIG. 15. Broomrape (*Orobanche*)—a total root-parasite. FIG. 16. *Balanophora*—a total root-parasite.

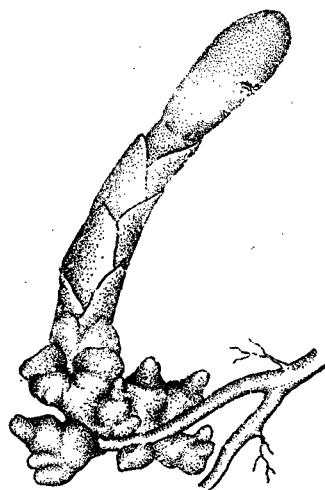

FIG. 16

food products. The following are some of the common examples of different types of parasites:

(1) Stem-parasites : (a) total—dodder; (b) partial—mistletoe, *Cassytha* and *Loranthus*.

(2) Root-parasites : (a) total—broomrape and *Balanophora*; (b) partial—sandal-wood tree. Broomrape is parasitic on roots of mustard, potato, tobacco, brinjal, etc., and *Balanophora* on roots of forest trees.

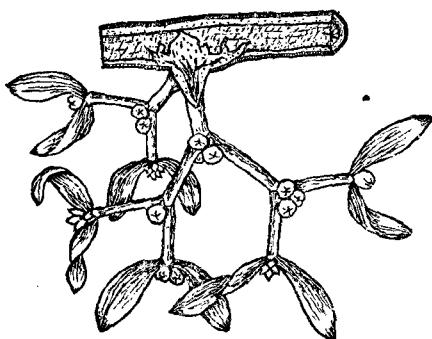

FIG. 17. Mistletoe—a partial stem-parasite.

Assam, bears the biggest flower in India. Each flower sometimes measures up to 0.3m. in diameter.

It may be of interest to note that *Rafflesia* (fig. 18), a total root-parasite found in Sumatra and Java, bears the biggest flower in the world. Each flower measures 0.5-1m. in diameter and weights over 8 kg. *Sapria*, similarly a total parasite found in the hills of

(2) **Saprophytes** (*sapros*, rotten; *phyta*, plants). These are plants that grow in soils rich in decaying organic substances of vegetable or animal origin, and derive their nutriment from them. They are non-green in colour. Among the 'flowering' plants Indian pipe (*Monotropa*; fig. 19) and some orchids afford good examples of saprophytes. *Monotropa* grows in the Khasi hills at an altitude of 1,800—2,500 metres.

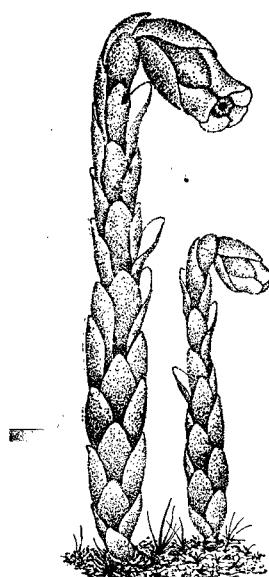

FIG. 19. Indian pipe (*Monotropa*)—a saprophyte.

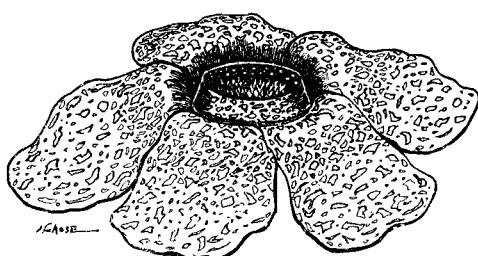

FIG. 18. *Rafflesia*—a total root-parasite.

(3) **Epiphytes** (*epi*, upon; *phyta*, plants). These are plants that grow on the stem and branches of other plants (see fig. 57), but do not suck them, i.e. do not absorb food from them, as do the parasites. They are green in colour. Many orchids, e.g. *Vanda* (B. & H. RASNA—see fig. 57) are epiphytes. They absorb moisture from the air and also trickling rain-water by their *hanging roots*, and absorb food from the humus that collects at the base of such plants by their *absorbing roots*. The hanging root has a covering of a special tissue, usually 4 or 5 layers in thickness, called **Velamen**, which acts like a sponge. Several mosses and ferns are also epiphytic.

(4) **Symbionts** (*syn*, together; *bios*, life). When two organisms live together, as if they are parts of the same plant, and are of mutual help to each other, they are

called **symbionts**, and the relationship between the two is expressed as **symbiosis**. Lichens are typical examples. These are associations of algae and fungi, and commonly occur as thin round greenish patches on tree-trunks and old walls. The alga in a lichen being green prepares food and shares it with the fungus, while the latter absorbs water and mineral salts from

the surrounding medium, and also affords protection to the algae.

(5) **Carnivorous Plants** (see part III chapter 8). Carnivorous plants are those that capture insects and small animals and feed upon them, absorbing only the nitrogenous compounds from their bodies. Such plants are green in colour and prepare their own carbonaceous food, while they partially depend on insects and other animals for nitrogenous food, e.g. sundew, Venus' fly-trap, *Aldrovanda*, pitcher plant and bladderwort.

CHAPTER 2 *Parts of a 'Flowering' Plant*

In response to division of labour (i.e. distribution of work) the plant body is primarily differentiated into the underground root system and the aerial shoot system. The former consists of the main root and the lateral roots, while the latter is differentiated into distinct organs such as the **stem**, **branches**, **leaves** and **flowers** (fig. 20). Of these the roots, stem, branches and leaves are called *vegetative parts*, and the flowers called *reproductive parts*. These organs have their respective functions and thus contribute to the life, existence and well-being of the plant as a whole, and to the continuation of the race.

Vegetative Parts. The **root system** normally lies underground and consists of the main root and the lateral roots. Each such root is tipped by a cap, called the **root-cap**, which protects the tender growing apex ; a little higher up the root bears a cluster of very fine and delicate hairs, called the **root-hairs**. The root system as a whole has two primary functions: *fixation* and *absorption*. The main root and the lateral roots firmly fix the plant to the ground ; while the root-hairs absorb water and raw food materials (mineral salts) from the soil. The **shoot system** (vegetative) on the other hand is normally aerial and consists of the main stem, its branches, and leaves. The main stem and its branches have two chief functions: *support* and *conduction*. These organs give support to the leaves and the flowers and spread them out on all sides, and they conduct water and food through the plant body. These organs, but not the roots, are provided with **nodes** and **internodes**. The leaf appears at the node and is provided with a stalk, called the

petiole, and a flat green expanded portion, the **leaf-blade** (or **-lamina**), which is interspersed with numerous **veins** of which

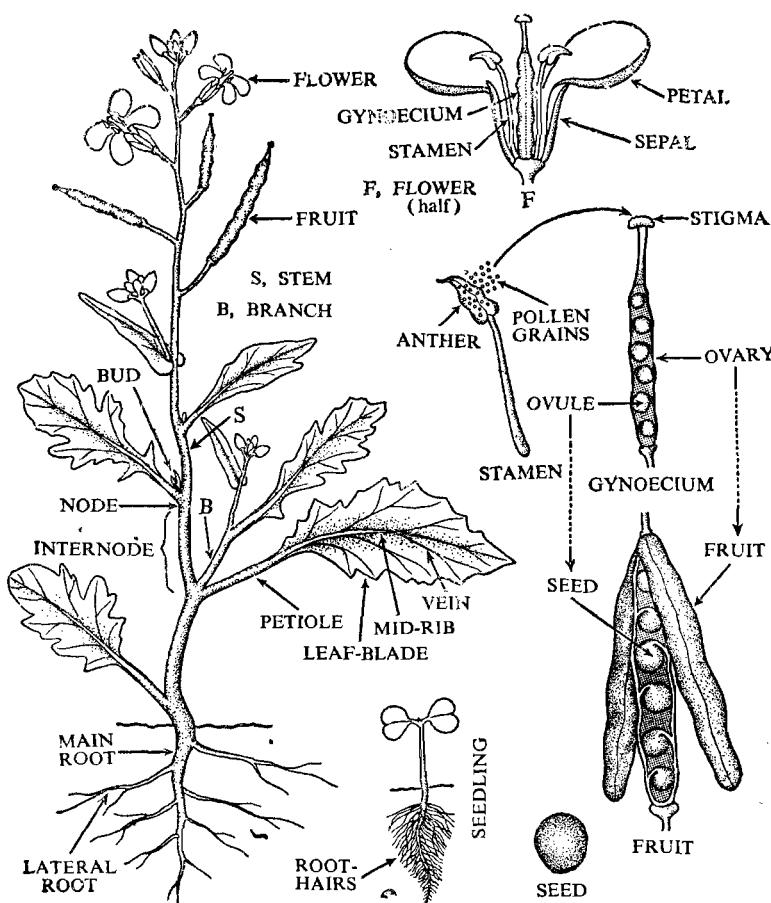

FIG. 20. Parts of a 'flowering' plant (mustard plant).

the median strong one is called the **mid-rib**. The green leaf-blade manufactures food, and is regarded as a very important vegetative organ. A **bud** appears in the axil of a leaf, and as it grows and elongates it gives rise to a branch. There is also a bud at the apex of the stem or the branch, and it is responsible for elongation of that organ by its continued growth.

Reproductive Parts. The **flower** is a highly specialized reproductive shoot. Each typical flower consists of *four* distinct

types of members arranged in *four* separate whorls or circles, one above the other, on the top of a long or short stalk. The first or the lowest one, often green in colour, is called the **calyx**, and each member of it a **sepal**. The second whorl, often brightly coloured, is called the **corolla**, and each member of it a **petal**. The corolla attracts insects from a distance by its bright colour. The third whorl of the flower is the male whorl, called the **androecium** (*andros*, male), and each member of it a **stamen**. The fourth or the uppermost whorl of the flower is the female whorl, called the **gynoecium** (*gyne*, female), and each member of it a **carpel**. The gynoecium may be made of one or more carpels, frequently two, united or free. In mustard flower (fig. 20) there are two carpels united together. Each stamen bears on its top a case, called the **anther**, which contains a mass of fine powdery or dust-like grains—the **pollen grains**. The gynoecium has a chamber at its base, called the **ovary**, which encloses some minute but complex egg-like bodies—the **ovules**, each with an **egg-cell** or ovum in it (see fig. 193). The top of the gynoecium is called the **stigma**.

Fruit, Seed, and Embryo. Some time after the pollen grains are carried over to the stigma, commonly by insects or wind, (see pollination, Chapter 10), the following important changes are noted: the ovary develops into the fruit, the ovule into the seed, and the egg-cell into the embryo. Later as the seed germinates, the embryo grows into a **seedling**.

CHAPTER 3 *The Seed*

Seeds soaked in water for a few hours or overnight should be studied by proper dissections under a simple microscope.

PARTS OF A GRAM SEED (fig. 21)

1. **Seed-coat.** The seed is covered by a brownish coat known as the **seed-coat**. It is made up of two layers or integuments, the outer one being called the **testa** and the inner one the **tegmen**. The testa is brownish in colour and is comparatively thick; while the tegmen is whitish, thin and membranous; it is fused with the testa. The seed-coat affords necessary protection to the embryo which lies within. On one side of the seed,

lying above its projected end, a small oval depression may be seen ; this is known as the **hilum**. The hilum represents the

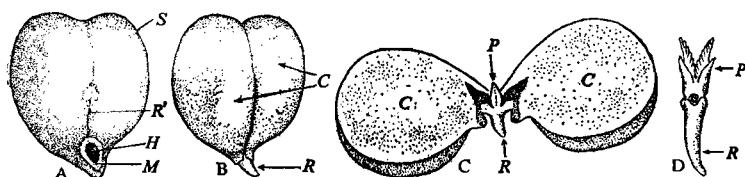

FIG. 21. Gram seed. *A*, entire seed; *B*, embryo (after removal of the seed-coat); *C*, embryo with the cotyledons unfolded; and *D*, axis of embryo. *S*, seed-coat; *R'*, raphe; *H*, hilum; *M*, micropyle; *C*, cotyledons; *R*, radicle; and *P*, plumule.

point of attachment of the seed to its stalk. Just below the hilum a very minute slit may be seen ; this minute slit or opening is known as the **micropyle** (*mikros*, small; *pyle*, a gate). When the soaked seed is gently pressed, water and minute air-bubbles are seen to escape through it. Above the hilum the stalk is continuous with the seed-coat forming a sort of ridge ; this ridge which is fused with the testa is called the **raphe**. Through the raphe food is supplied to the embryo.

(2) **Embryo.** The yellowish body, as seen after removing the seed-coat, is the **embryo** or the baby plant. As the seed germinates it gives rise to a seedling which gradually develops into the gram plant. The embryo consists of *two* white fleshy bodies, known as (a) the **cotyledons** or seed-leaves, and (b) a short **axis** to which the cotyledons are attached. The part of the axis lying towards the pointed end of the seed is called (i) the **radicle** (a little root), while the other end lying in between the two cotyledons is known as (ii) the **plumule** (*plumula*, a small feather). The plumule is surrounded at the apex by a number of minute leaves, and as such it looks more or less like a small feather. As the seed germinates the radicle gives rise to the root and the plumule to the shoot. Cotyledons store up food material.

Gram Seed—
—seed-coat with testa, hilum, micropyle, raphe and tegmen.
—embryo—|—axis with radicle and plumule.
—cotyledons—2, fleshy, laden with food.

PARTS OF A PEA SEED (fig. 22)

Seed-coats. The seed is somewhat roundish in shape, and is covered by two distinct **seed-coats**. Of the two coats the outer

whitish one is called the **testa**; it comes off easily when the seed is soaked in water. The testa encloses another coat which

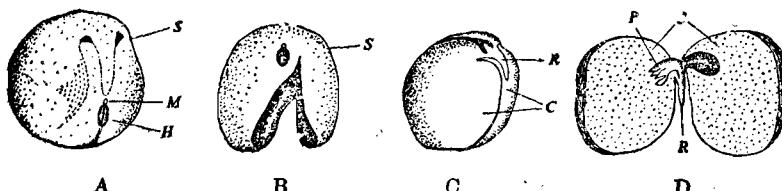

FIG. 22. Pea seed. *A*, entire seed; *B*, seed-coat with hilum and micropyle; *C*, embryo (after removal of the seed-coat); *D*, embryo with the cotyledons unfolded. *S*, seed-coat—testa (it encloses a thin membranous tegmen); *M*, micropyle; *H*, hilum; *R*, radicle; *C*, cotyledons; *P*, plumule.

is loose, thin, hyaline and membranous; this inner coat is called the **tegmen**. The seed-coats give necessary protection to the embryo which lies within. On one side of the testa a narrow, elongated scar representing the point of attachment of the seed to its stalk is distinctly visible; this is the **hilum**. Close to the hilum situated at one end of it there is a minute hole; this is the **micropyle**. On germination of the seed the radicle comes out through it. Continuous with the hilum there is a sort of ridge in the testa; this is the **raphe**.

2. Embryo. The whitish fleshy body, as seen after removing the seed-coats, is the **embryo**. It consists of (*a*) two fleshy **cotyledons** or seed-leaves and (*b*) a short **axis** to which the cotyledons remain attached. The portion of the **axis** lying outside the cotyledons, bent inwards and directed towards the micropyle, is (*i*) the **radicle**, the other portion of the axis lying in between the two cotyledons is (*ii*) the **plumule**. The plumule is crowned by some minute young leaves. The radicle gives rise to the root, the plumule to the shoot, and the cotyledons store up food material.

Pea Seed—
—seed-coats with testa, hilum, micropyle, raphe and tegmen.
—embryo—
—cotyledons—2, fleshy, laden with food.

PARTS OF A COUNTRY BEAN SEED (fig. 23)

1. Seed-coat. The country bean seed (*Dolichos lablab*; B. SHIM; H. SEM) is more or less oval, and is covered by a blackish or reddish, hard **seed-coat**. The seed-coat consists of two layers fused together, the outer one being known as the **testa** and the inner one the **tegmen**. At one edge of the seed-coat there is a

whitish, elongated ridge ; this ridge is called the **raphe**. At the basal portion of the raphe there is a distinct broad scar ; this is

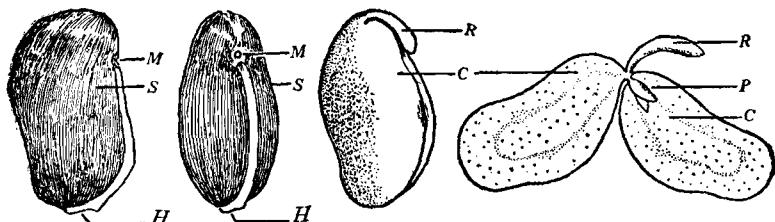

FIG. 23. Country bean seed. *M*, micropyle; *S*, seed-coat; *H*, hilum; *R*, radicle; *C*, cotyledons; *P*, plumule.

the **hilum**. At the other end of the raphe away from the hilum there is a minute but distinct hole ; this is the **micropyle**. If the soaked seed be gently pressed, water and minute air-bubbles are seen to ooze out through it.

2. Embryo. On peeling off the seed-coat a distinct, white, fleshy body is seen occupying the whole space within the seed-coat ; this is the **embryo**. It consists of (*a*) two fleshy **cotyledons** and (*b*) an **axis** to which the cotyledons remain attached. The portion of the axis lying externally with its apex directed towards the micropyle is (*i*) the **radicle**, and the other portion of the axis lying in between the two cotyledons and composed of minute, young leaves is (*ii*) the **plumule**.

PARTS OF A CASTOR SEED (fig. 24)

1. Seed-coats. The hard and blackish shell is the outer seed-coat or **testa**. At one end of the seed-coat there is a white body, an outgrowth formed at the micropyle, called the **caruncle**. Nearly hidden by the caruncle a small scar may be seen on the seed-coat, representing the point of attachment of the seed to its stalk ; this is the **hilum**. On removing the testa a thin and membranous inner seed-coat or **tegmen** may distinctly be seen surrounding the endosperm. Running down from the hilum a ridge may be seen on the outer seed-coat or testa ; this ridge has been formed by the fusion of the stalk with the testa, and is known as the **raphe**.

2. Endosperm (*endo*, inner or within ; *sperm*, seed). Remove the seed-coats and note, lying inside them, a white, fleshy mass ; this is the **endosperm**. It is the food storage tissue of the seed, particularly rich in oil. It encloses the embryo.

3. **Embryo.** This lies embedded in the endosperm. Split open the endosperm and observe that the embryo consists of (a) two thin,

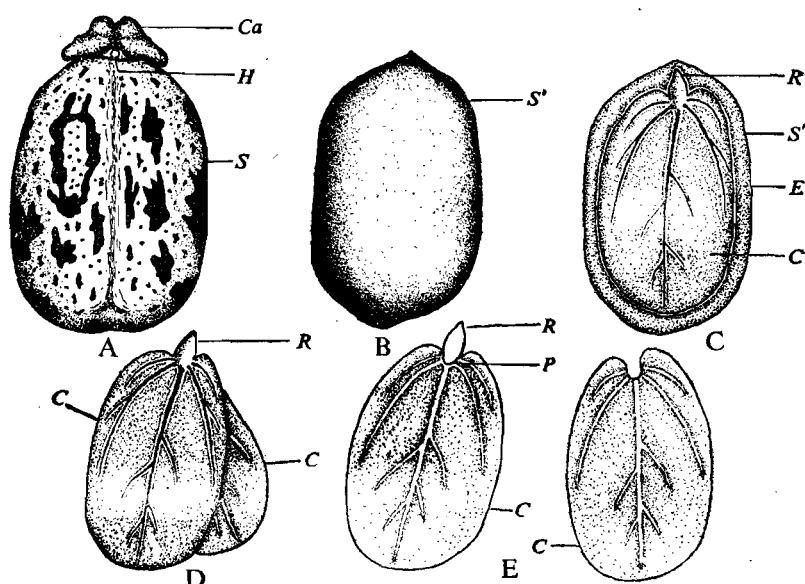

FIG. 24. Castor seed. *A*, an entire seed; *B*, endosperm surrounded by tegmen; *C*, the same split open lengthwise; *D*, embryo separated from the endosperm; *E*, cotyledons separated. *Ca*, caruncle; *H*, hilum; *S*, testa; *S'*, tegmen; *R*, radicle; *E*, endosperm; *C*, cotyledons; *P*, plumule.

flat and papery **cotyledons** or seed-leaves, more or less distinctly marked by veins, and (b) a very short **axis**; the axis consists of (i) a **radicle** which is a little protuberance towards the caruncle, and (ii) an undifferentiated **plumule** which is the blunt inner end of the axis lying in between the two cotyledons. The minute leaves of the plumule become apparent only when the seed begins to germinate. The radicle always gives rise to the root and the plumule to the shoot. Cotyledons lie embedded in the endosperm, and their function is to transport the food material from the endosperm to the radicle and the plumule, and later, on the germination of the seed, they turn green and leafy (see fig. 28).

Castor Seed—
 —seed-coats with testa, hilum, caruncle, raphe and tegmen.
 —endosperm laden with food.
 —embryo—|—axis with radicle and plumule.
 —cotyledons—2, thin, leaf-like.

PARTS OF A RICE GRAIN (fig. 25)

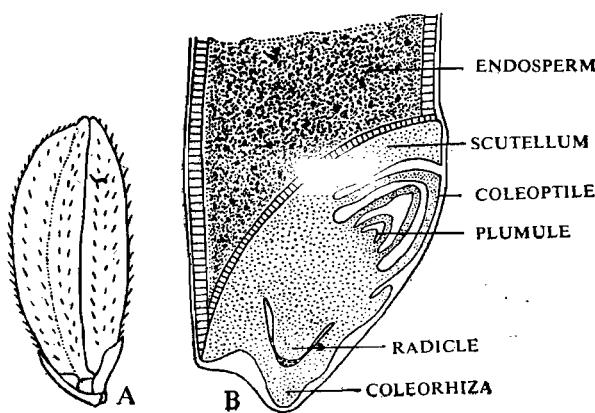

Rice grain is a small, one-seeded fruit. Each grain remains enclosed in a brownish husk which consists of two parts, one partially enveloping the other; the outer and larger one is called the *flowering glume*, while the inner and smaller one is called the *palea*. At the base of the grain are two minute white scales called *empty glumes*. The rice grain and the husk are together known as the paddy grain.

1. **Seed-coat.** On removing the husk a brownish membranous layer is seen adherent to the grain. This layer is made up of the seed-coat and the wall of the fruit fused together.

2. **Endosperm.** This forms the main bulk of the grain and is its food storage tissue, being laden with reserve food material, particularly starch. In a longitudinal section of the grain it is seen to be distinctly separated from the embryo by a definite layer known as the *epithelium*.

3. **Embryo.** This is very small and lies in a groove at one end of the endosperm. It consists of only (a) one shield-shaped cotyledon which is known as the **scutellum**, and (b) a short **axis** which has an upper portion (i) the **plumule**, and a lower portion

FIG. 25.
Rice grain.
A, the grain
enclosed in
husk ;
B, the grain
in longitudi-
nal section
(a portion).

(ii) the **radicle**. The plumule is surrounded by minute leaves, and the radicle is protected by a cap known as the **root-cap**. The plumule as a whole (growing point and foliage leaves) is surrounded and protected by a plumule-sheath, called **coleoptile**; similarly the radicle is surrounded by a root-sheath, called

coleorhiza. The surface layer of the scutellum lying in contact with the endosperm is the **epithelium**; its function is to digest and absorb food material stored in the endosperm.

PARTS OF A MAIZE GRAIN (fig. 26)

Like the previous one the maize grain is also a small, one-seeded fruit. The seed is adherent to the wall of the fruit and not separable from it. On one side of the grain a small, opaque, whitish, deltoid area is distinctly seen. The embryo lies embedded in this area. The grain cut longitudinally through this area shows the following:

1. **Seed-coat.** This is only a thin layer surrounding the whole grain. This layer is made up of the seed-coat and the wall of the fruit fused together.
2. **Endosperm.** The grain is divided into two unequal portions by a definite layer known as the *epithelium*. The bigger portion is the endosperm, and the smaller portion is the embryo. The endosperm is the food storage tissue of the grain, particularly rich in starch. If a little iodine solution be put on the cut surface of the grain the whole of the endosperm becomes black indicating the presence of starch; the embryo takes on a yellowish tinge. Thus the two portions become clearly marked.

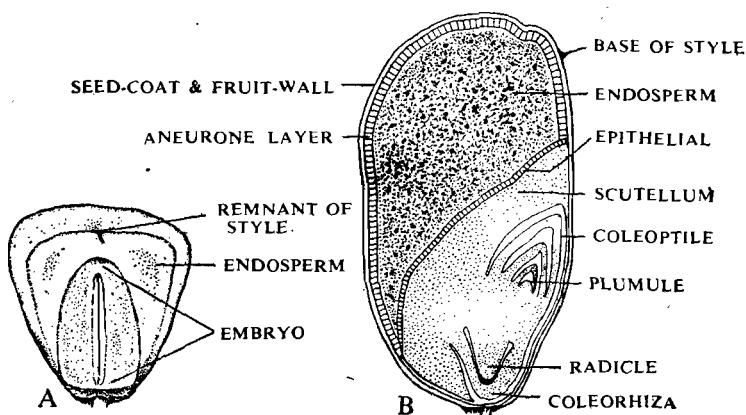

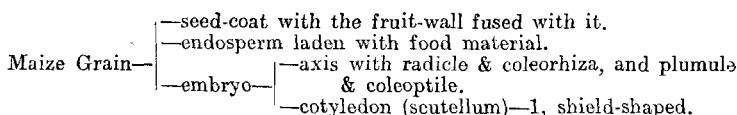

FIG. 26. Maize grain.
A, the entire grain; B, the grain in longitudinal section.

3. **Embryo.** This consists of (a) one shield-shaped cotyledon, known as the **scutellum**, as in the rice grain, and (b) an **axis**. The upper portion of the axis, with minute leaves arching over it, is (i) the **plumule**, and the lower portion, provided with

the **root-cap**, (ii) the **radicle**. The plumule is surrounded by a plumule-sheath or **coleoptile**, and the radicle is surrounded by a root-sheath or **coleorhiza**. Coleoptile and coleorhiza are protective sheaths of the plumule and the radicle respectively, and are characteristic of the grass family and the palm family. The surface layer of the scutellum lying in contact with the endosperm is the *epithelium*; its function is to digest and absorb food material stored in the endosperm.

Note. In cereals (e.g. rice, wheat, maize, barley and oat), millets and other plants of the grass family the cotyledon is known as the **scutellum**. It supplies the growing embryo with food material absorbed from the endosperm with the help of the *epithelium*.

Dicotyledonous and Monocotyledonous Seeds. It must have been noted from studies of the foregoing seeds that some of them, e.g. gram, bean, pea, castor, etc., bear *two cotyledons* in their embryo ; while others, e.g. rice, maize, etc., bear only *one cotyledon* in their embryo. The former types of seeds are said to be dicotyledonous, and the latter monocotyledonous. On the basis of this and other characters the 'flowering' plants have been divided into two big classes: **dicotyledons** (with two cotyledons) and **monocotyledons** (with one cotyledon). Dicotyledons far outnumber monocotyledons.

Albuminous and Exalbuminous Seeds. (1) Seeds that possess a special food storage tissue, called the endosperm, are said to be **albuminous** or endospermic, and those that possess no such special tissue for food storage are said to be exalbuminous or non-endospermic. Monocotyledonous seeds are mostly albuminous ; while among dicotyledons both are common.

(2) In all seeds the food accumulates in the endosperm tissue at an early stage of seed-development. But in albuminous seeds the endosperm continues to store food and to enlarge rapidly. Ultimately in the mature seed it acts as the food storage tissue. In exalbuminous seeds on the other hand the food that accumulates in the endosperm tissue at an early stage of seed-development is utilized by the developing embryo so that the endosperm becomes exhausted.

(3) In albuminous seeds food being stored in the endosperm the cotyledons are small and thin, while in exalbuminous seeds the cotyledon(s) store up food and become thick and fleshy. The food whether stored in the endosperm or in the cotyledon(s) is always utilized by the embryo when germination of the seed takes place.¹

Dicotyledonous Seeds

(a) Exalbuminous, e.g., gram, pea, bean, gourd, tamarind, mustard, mango, cotton, orange, pulses, sunflower, guava, jack, etc.

(b) Albuminous, e.g., castor, poppy, papaw, custard-apple, four o'clock plant, etc.

Monocotyledonous Seeds

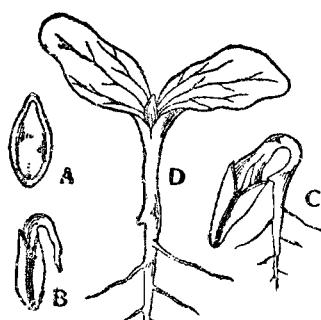

(a) Exalbuminous, e.g., orchids, *Alisma*, arrowhead and *Naias*.

(b) Albuminous, e.g., cereals (rice, wheat, oat, maize and barley), millets, grasses (including sugarcane and bamboo), palms, lilies, aroids, etc.

GERMINATION

The embryo lies dormant in the seed, but when the latter is supplied with moisture the embryo becomes active and tends to grow and develop into a small seedling. *The process by which the dormant embryo wakes up and begins to grow is known as germination.* At first the seed absorbs moisture and swells up considerably. Then the radicle elongates and comes

out often through the micropyle and gives rise to the root. The radicle always grows downwards, often forming a loop, and gives rise to the root system; its rate of growth is much faster than that of the plumule. As a result of swelling, the seed-coat bursts and the cotyledons partially or completely separate from each other. The plumule comes out, grows upwards and gives rise to the shoot. Commonly the cotyledons turn green and in most

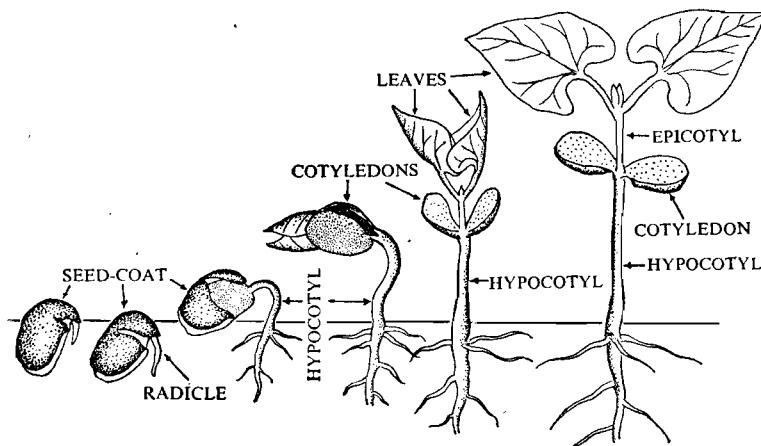

Epigeal Germination.

FIG. 27A. Gourd seed.

cases, become leaf-like in appearance. In some cases, however, they are seen to shrivel up and drop. Two kinds of germination will be noticed: epigeal and hypogea.

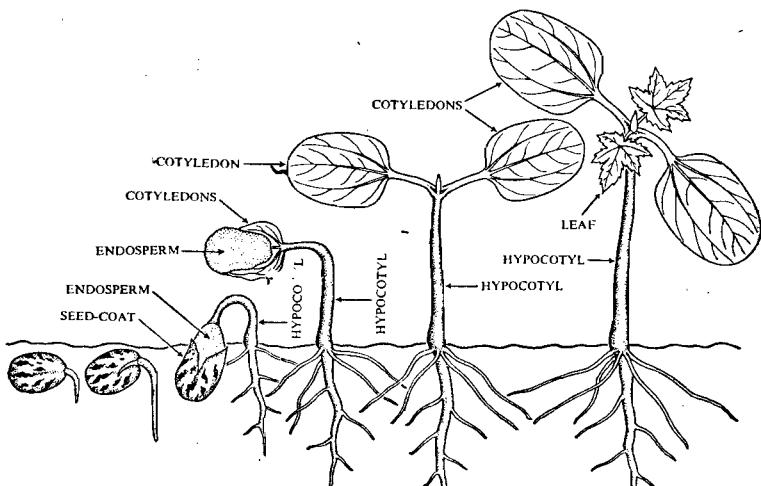

¹ For 'food stored in the seed' see end of Chapter 8, Part III.

1. **Epigeal Germination** (figs. 27-8). In some seeds, such as bean, gourd, tamarind, castor, cotton, etc., the cotyledons are seen to be pushed upwards by the rapid elongation of the **hypocotyl**

Epigeal Germination. FIG. 27B. Country bean seed.

(*hypo*, below), i.e. the portion of the axis lying immediately below the cotyledons. Germination of this kind is said to be **epigeal** (*epi*, upon ; *ge*, earth).

Epigeal Germination. FIG. 28. Castor seed (albuminous).

2. **Hypogeal Germination** (figs. 29-30). In other seeds such as gram, pea, mango, litchi, jack, groundnut, etc., the cotyledons

are seen to remain in the soil or just on its surface. In such cases the **epicotyl**, i.e. the portion of the axis lying immediately above the cotyledons, elongates and pushes the plumule upwards. The cotyledons do not turn green, but gradually dry up and fall off. Germination of this kind is said to be **hypogean** (*hypo*, below; *ge*, earth).

Hypogean
Germination.

FIG. 29.
Gram seed.

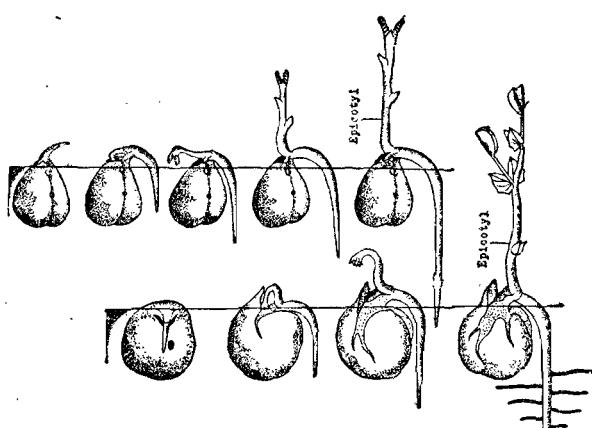

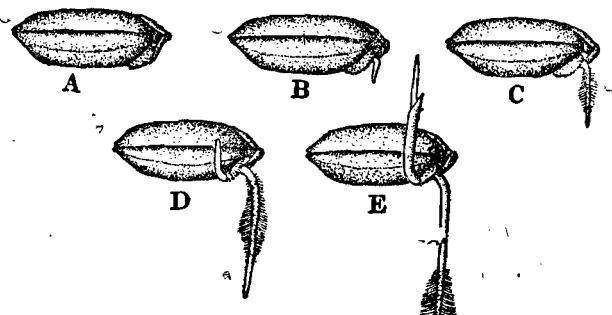

FIG. 30.
Pea seed.

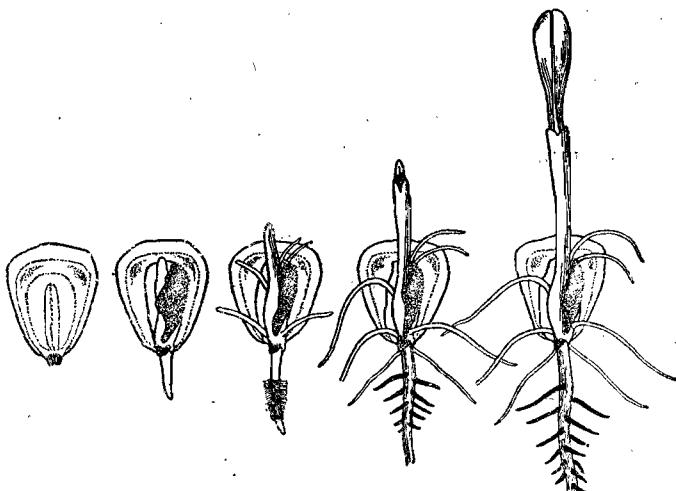

Hypogean Germination of Monocotyledonous Seeds (figs. 31-2). Monocotyledonous seeds are mostly albuminous and in their germination the cotyledon and endosperm remain buried in

Hypogean Germination FIG. 31. Paddy.

the soil; germination is, therefore, hypogean (except in the case of onion). In the germination of monocotyledonous seeds like paddy and maize (figs. 31-2), the radicle makes its way through the lower short, collar-like end of the sheath called the root-sheath or **coleorhiza**; while the plumule breaks through the upper distinct, cylindrical portion of the sheath

called the plumule-sheath or **coleoptile**. The radicle grows

Hypogaeal Germination. FIG. 32. Maize grain.

downwards into the primary root, but this is soon replaced by a cluster of fibrous roots. The plumule grows upwards. In the germination of many palms, e.g. date-palm and palmyra-palm (but not coconut-palm) a part of the cotyledon extends into a sheath, long or short, which encloses the axis of the embryo a little behind the tip and carries it down to some depth in the soil (see fig. 34).

Special Type of Germination.

Many plants growing in salt-lakes and sea-coasts show a special type of germination of their seeds, known as **vivipary** (fig. 33). The seed germinates inside the fruit while still attached to the parent tree and nourished by it. The radicle elongates, swells in the lower part and gets stouter. Ultimately the seedling separates from the parent plant due to its increasing weight, and falling vertically becomes embedded in the

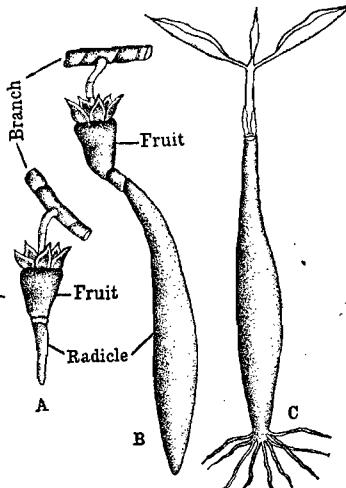

FIG. 33. Viviparous germination.
A-B, stages in germination;
C, seedling.

soft mud below. The radicle presses into the soil, and quickly lateral roots are formed for proper anchorage. Examples are seen in *Rhizophora* (B. KHAMO), *Sonneratia* (B. KEORA), *Heritiera* (B. SUNDRI), etc.

Conditions necessary for Germination. (1) **Moisture.** For germination of a seed water is indispensable; the protoplasm becomes

active only when it is saturated with water. In air-dried seeds water content is usually 10-15%. No vital activity is possible at this low water content. Water facilitates the necessary chemical changes in food materials, and it also softens the seed-coat.

(2) **Temperature.** A suitable temperature is necessary for the germination of a seed. Protoplasm functions normally within a certain range of temperature. Within limits the higher the temperature the more rapid is the germination.

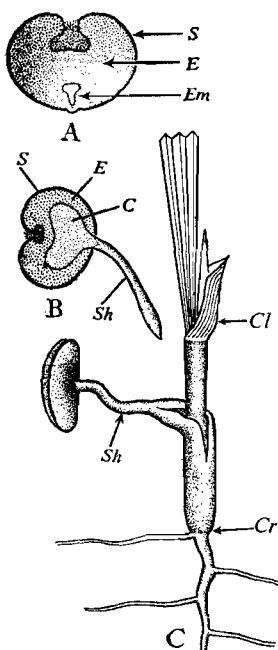

(3) **Air.** Oxygen of the air is necessary for respiration of a germinating seed. The process liberates energy from the stored food and activates the protoplasm. The germinating seed respires very vigorously.

It may be noted in this connexion that **light** is not an essential condition of germination. In fact seeds germinate more quickly in the dark. For subsequent growth, however, light is indispensable.

FIG. 34. Date-palm seed and its germination. A, seed in section; B, germinating seed in section; C, seedling. S, seed-coat and inner fruit-wall; E, endosperm; Em, embryo (undifferentiated); C, cotyledon; Sh, sheath of the cotyledon; Cl, coleoptile; Cr, coleorhiza.

Seedlings grown continually in the dark elongate rapidly but become very weak, develop no chlorophyll and bear only pale, undeveloped leaves (see fig. 349).

Three Bean Experiment (fig. 35). That all the conditions mentioned above are essential for germination can be shown by a simple experiment, known as the **three bean experiment**. Three air dry seeds are attached to a piece of wood, one at each end and one in the middle. This is then placed in a beaker, and water is poured into it until the middle seed is half

immersed in it. The beaker is then left in a warm place for a few days. From time to time water is added to maintain the original level. It is seen that the middle bean germinates normally because it has sufficient moisture, oxygen and heat. The bottom bean has sufficient moisture and heat, but not oxygen. It may be seen to put out the radicle only, but further development is checked for want of oxygen. The top bean having only sufficient oxygen and heat, but not moisture, does not show any sign of germination.

This experiment evidently shows that moisture and oxygen are indispensable for germination; the effect of temperature is only indirectly proved. It can, however, be directly proved in the following way. Other conditions remaining the same, if the temperature be considerably lowered or increased by placing the beaker with the seeds in a freezing mixture or in a bath with constant high temperature it will be seen that none of the beans will germinate. Thus suitable temperature is also an essential condition for germination.

FUNCTIONS OF COTYLEDONS

(1) In exalbuminous seeds, as in gram, pea, gourd, tamarind, etc., the cotyledons act as food storage organs and in consequence they become thick and fleshy. The food stored in them is utilized by the embryo when the seed germinates.

(2) In albuminous seeds, as in castor, poppy, four o'clock plant, etc., the cotyledons act as absorbing organs, and they are thin, flat or small. When the seed germinates they absorb food from the endosperm and supply it to the radicle and the plumule.

(3) In many seeds showing epigeal germination (i.e. lifting the cotyledons above the ground) the cotyledons may act as food-manufacturing organs. When they are pushed above the ground they generally turn green in colour being exposed to light and then function like ordinary leaves, i.e. they manufacture food in the presence of sunlight.

(4) The cotyledons act as protective organs. They lie on either side of the plumule, and at the seed stage and during the early germination period they give it adequate protection.

(5) In monocotyledonous seeds at the time of germination the cotyledon absorbs food from the endosperm, and at length extends as a sort of sheath, long or short, pushing the radicle and the plumule out of the seed. In many palms, as in

FIG. 35. Three bean experiment.

palmyra-palm and date-palm (but not coconut-palm) a fairly long sheath is produced (see fig. 34).

CHAPTER 4: *The Root*

The **root** is the descending organ of the plant, and is originally the direct prolongation of the radicle of the embryo. It grows downwards, fixes the seedling and later the plant as a whole to the ground, and absorbs raw food materials (water and in-

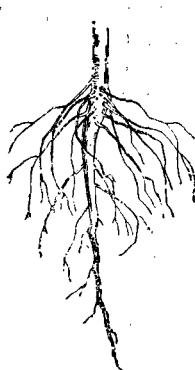

FIG. 36

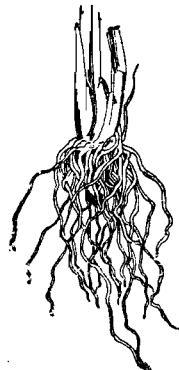

FIG. 37

FIG. 38

FIG. 39

organic salts) from the soil particles. It is non-green in colour, without nodes and internodes, leaves or buds, and is covered at its tip, i.e. the growing point, by a sort of cap known as the **root-cap** (fig. 41).

Normal Roots. All roots that develop from the radicle, either directly from it or as its branches, are called normal roots. The direct prolongation of the radicle forms the **primary root**. If it persists and continues to grow, as in dicotyledons, giving rise to the main root of the plant it is called the **tap root** (fig. 36). The tap root normally grows vertically downwards to a shorter or longer depth. As it grows it produces lateral branches known as the *secondary roots*, and these in turn produce the *tertiary roots*. All these roots together form the **tap root system** of the plant. The lateral roots are produced in *acropetal* succes-

sion, i.e. older and longer roots away from the tip, and younger and shorter ones towards it.

Adventitious Roots. Roots that grow from any part of the plant body other than the radicle are called adventitious roots. (1) In monocotyledons where the primary root does not persist, a cluster of slender roots is seen to grow from the base of the stem; such roots are called **fibrous roots** (fig. 37). (2) Adventitious roots, solitary or in clusters, also grow from nodes and even internodes, as in many grasses, betel, wood-sorrel, sugarcane, maize, bamboo, etc. (3) They also often grow from stem-cuttings (fig. 40), as in *Coleus*, rose, garden croton, etc. (4) Adventitious roots, called **foliar roots** (see fig. 350), may also be induced to grow from the petiole or vein of a leaf by the application of certain chemicals, called *hormones*, which are growth-promoting substances.

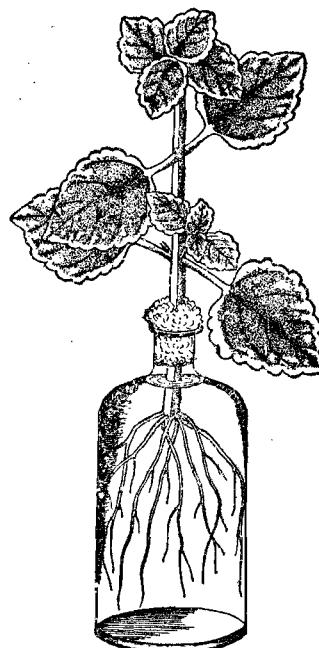

FIG. 40. Adventitious roots in *Coleus*.

Regions of the Root (fig. 41). The following regions may be distinguished in a root from the apex upwards. There is of course no line of demarcation between one region and the other. As a matter of fact one merges into the other.

1. **Root-cap.** Each root is covered over at the apex by a sort of cap or thimble known as the root-cap which protects the tender apex of the root as it makes its way through the soil. The root-cap, if worn out, may be renewed by the underlying growing tissue. It is usually absent in aquatic plants.

2. **Region of Cell Division.** This is the growing apex of the root lying within and a little beyond the root-cap and extends to a length of a few millimetres. The cells of this region undergo repeated divisions, and hence this region is otherwise called the

meristematic region (*meristos*, divided). Some of the newly formed cells contribute to the formation of the root-cap and others to the next upper region.

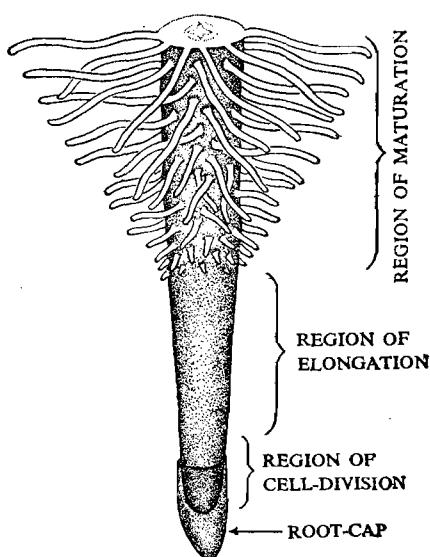

FIG. 41. Regions of the root.

Root-hairs, and above the root-hair region it produces **lateral roots**, both in *acropetal* succession. The root-hairs are essentially meant to absorb water and mineral salts from the soil. Internally, the cells of this region are seen to undergo maturation and differentiation into various kinds of primary tissues. Higher up it gradually merges into the region of secondary tissues.

Characteristics of the Root. There are certain distinctive characteristics of the root by which it can be distinguished from the stem. These are as follows:

(1) The root is the descending organ of the plant and the primary root is the direct prolongation of the radicle; whereas the stem is the ascending organ of the plant and the direct prolongation of the plumule. Roots grow downwards and away from light; whereas the stem grows upwards and towards light. Roots are not normally green in colour; whereas the young stem is normally so.

(2) The root does not normally bear **buds**; while the stem normally bears both vegetative and floral buds for vegetative

3. Region of Elongation.

This lies above the meristematic region and extends to a length of a few millimetres. The cells of this region undergo rapid elongation and enlargement, and are responsible for growth in length of the root.

4. Region of Maturation.

This region lies above the region of elongation and extends upwards. Externally, at its basal portion, this region produces a cluster of very fine and delicate thread-like structures known as the **root-hairs**, and above the root-hair region it produces **lateral roots**,

both in *acropetal* succession. The root-hairs are essentially

meant to absorb water and mineral salts from the soil. Internally,

the cells of this region are seen to undergo maturation

and differentiation into various kinds of primary tissues.

Higher up it gradually merges into the region of secondary

tissues.

growth and reproduction. There are, however, cases where the roots are seen to bear vegetative buds (but not floral buds) for vegetative propagation, e.g. sweet potato, wood-apple, *Trichosanthes* (B. PATAL; H. PARWAL), Indian redwood (B. SISOO;

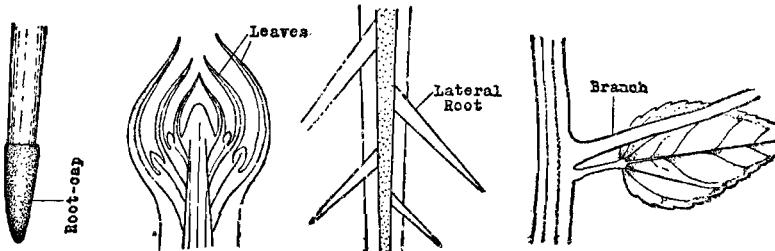

FIG. 42 FIG. 43 FIG. 44 FIG. 45

FIG. 42. Root-tip. FIG. 43. Stem-apex. FIG. 44. Lateral root (endogenous; see also FIG. 311). FIG. 45. Branch (exogenous).

H. SHISHAM), and ipecac. Such plants are sometimes propagated by root-cuttings, e.g. ipecac (a medicinal plant).

(3) The root ends in and is protected by a cap- or thimble-like structure known as the **root-cap** (fig. 42); while the stem ends in a bud—the terminal bud (see fig. 59B). A distinct, multiple root-cap is seen in the aerial root of screwpine (B. KETUCKY; H. KEORA—fig. 38).

In water plants like duckweed, water lettuce, water hyacinth, etc., a loose sheath which comes off easily is distinctly seen at the apex of each root. This is an anomalous root-cap, called the **root-pocket** (fig. 39).

(4) The root bears **unicellular hairs** (fig. 46A-B); while the stem or the shoot bears mostly **multicellular hairs** (fig. 46C). Root-hairs occur in a cluster all over the tender part of the young root a little behind the root-cap. But as the root grows, older root-hairs die off and newer ones are always formed close behind the apex. Shoot-hairs, on the other hand, are of various kinds and they remain scattered over the surface of the shoot. Root-hairs have very thin walls made of cellulose; while shoot-hairs are somewhat thickened and cutinized, at least at the base. Root-hairs are short-lived, usually persisting for a few days or weeks; while shoot-hairs last for a much longer time. Root-hairs absorb water and mineral salts from the soil, and shoot-hairs prevent evaporation of water from the surface of the plant body and afford protection.

(5) Lateral roots always develop from an inner layer (fig. 44); so they are said to be **endogenous** (*endo*, inner; *gen*, producing).

Branches, on the other hand, develop from a few outer layers (fig. 45) ; so they are said to be **exogenous** (*exo*, outer).

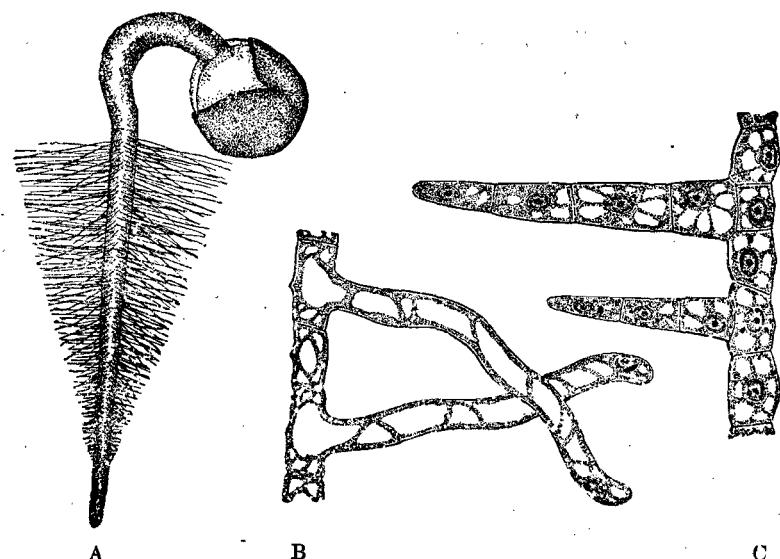

FIG. 46. A, root-hairs in mustard seedling; B, two root-hairs (magnified)—unicellular; C, two shoot-hairs (magnified)—multicellular.

(6) **Nodes** and **internodes** are always present in the stem, although they may not often be quite distinct ; but in the root they are absent.

MODIFIED ROOTS

Specialized functions of varied nature are performed by the modified roots which adapt themselves according to the particular need of the plant. For these purposes both the tap root and the adventitious roots may undergo modifications. The following are a few such cases.

A. MODIFIED TAP ROOT (for storage of food)

1. **Fusiform Root** (fig. 47). When the root is swollen in the middle and gradually tapering towards the apex and the base, being more or less spindle-shaped in appearance, it is said to be fusiform, e.g. radish.

2. **Napiform Root** (fig. 48). When the root is considerably swollen at the upper part becoming almost spherical, and

sharply tapering at the lower part, it is said to be napiform, e.g. turnip and beet.

- Modified Roots.
 FIG. 47. Fusiform root of radish.
 FIG. 48. Napiform root of turnip.
 FIG. 49. Conical root of carrot.

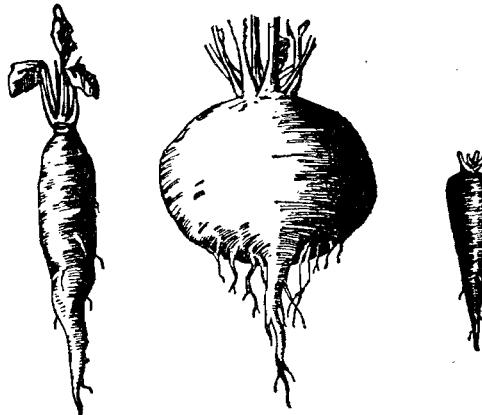

FIG. 47

FIG. 48

FIG. 49

3. **Conical Root** (fig. 49). When the root is broad at the base and it gradually tapers towards the apex like a cone, it is said to be conical, e.g. carrot.

4. **Tuberous or Tubercular Root**. When the root is thick and fleshy but does not maintain any particular shape, it is said to be tuberous or tubercular, as in four o'clock plant.

B. MODIFIED ADVENTITIOUS ROOTS

(a) for storage of food

1. **Tuberous or Tubercular Root** (fig. 50). This is a swollen root without any definite shape, as in sweet potato. Tuberous roots,

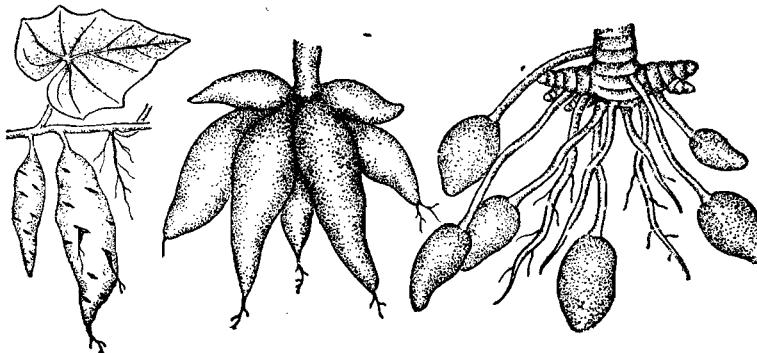

FIG. 50

FIG. 51

FIG. 52

FIG. 50. Tuberous roots of sweet potato. FIG. 51. Fasciculated roots of *Dahlia*. FIG. 52. Nodulose roots of mango ginger.

whether tap or adventitious, are produced singly and not in clusters.

2. Fasciculated Roots (fig. 51). When several tubercular roots occur in a cluster or fascicle at the base of the stem, they are said to be fasciculated, as in *Dahlia*, *Ruellia* and *Asparagus*.

3. Nodulose Root (fig. 52). When the slender root becomes suddenly swollen near the apex, it is said to be nodulose, as in mango ginger (B. AMADA ; H. AM-HALDI) and arrowroot.

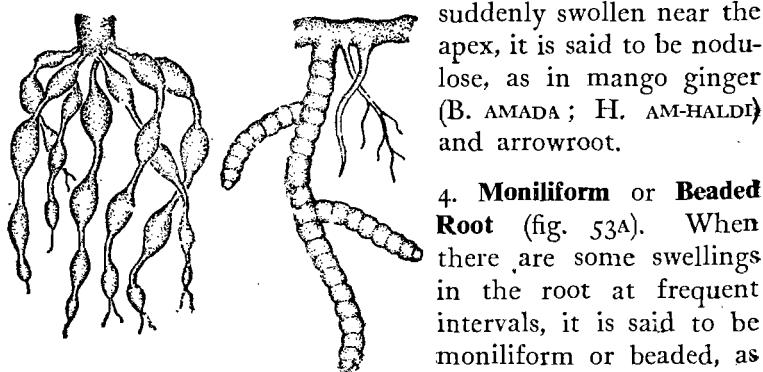

FIG. 53. A, moniliform roots of *Momordica*; B, annulated roots of ipecac. *Momordica* (B. KAKROL ; H. CHATTI), wild vine (B. AMAL-LATA ; H. AMALBEI) and some grasses.

5. Annulated Root (fig. 53B). When the root has a series of ring-like swellings on its body, it is said to be annulated, as in ipecac.

(b) for mechanical support

6. Prop or Stilt Roots (fig. 54-5). In plants like banyan, India rubber plant, screwpine, *Rhizophora*, etc., a number of roots are produced from the main stem and often from the branches. These roots grow vertically or obliquely downwards and penetrate into the soil. Gradually they get stouter and act as pillars supporting the main stem and the branches or the plant as a whole. Such roots are known as **prop** or **stilt roots**. The big banyan tree of the Indian Botanic Garden near Calcutta has produced near about 900 such roots from its branches. Its age is estimated to be about 200 years, and the circumference of the crown over 360 metres.

7. Climbing Roots (fig. 56A). Climbing plants like betel, long pepper, black pepper, *Pothos*, etc., produce roots from their

nodes and often from the internodes, by means of which they attach themselves to their support and climb it. To ensure a foothold such roots secrete a kind of sticky juice which quickly dries up in the air, as seen in ivy and Indian ivy (see fig. 1).

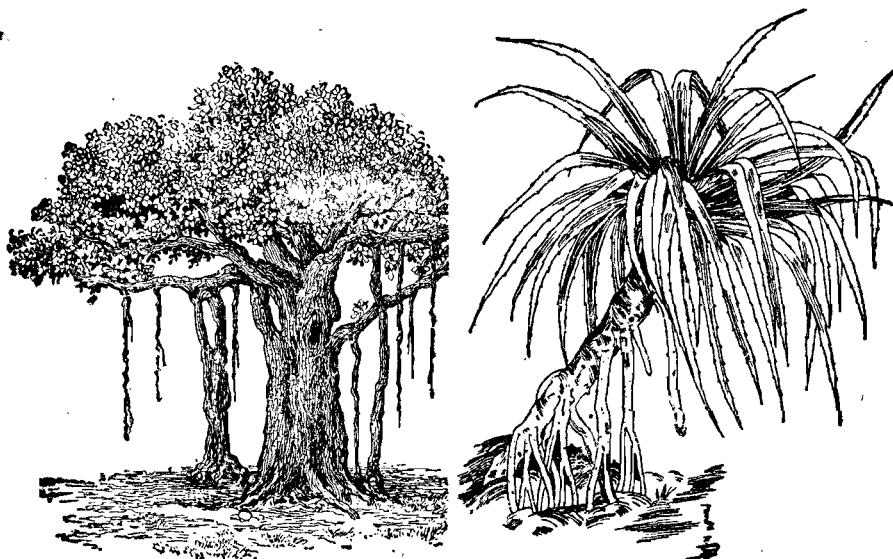

FIG. 54

FIG. 55

FIG. 54. Prop or stilt roots of banyan. FIG. 55. The same of screwpine.

Often they form at their apex a sort of disc or claw for firmer foothold. Such roots are also called **clinging roots**.

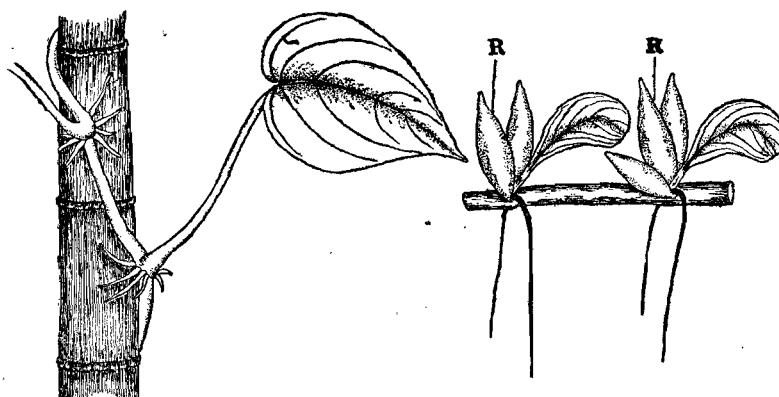

FIG. 56. A, climbing roots of betel; B, respiratory roots (R) of *Jussiaea*.

(c) for vital functions

8. Sucking Roots or Haustoria (see figs. 13-14). Parasites develop certain kinds of roots which penetrate into the tissue of the

host plant and suck it. Such roots are known as sucking roots or haustoria (sing. haustorium). Parasites, particularly non-green ones, have to live by sucking the host plant, i.e. by absorbing food from it with the help of their sucking roots. Common examples are dodder (see fig. 13), broomrape (B. BANIA-BAU; see fig. 15), mistletoe (B. BANDA; H. BHANGRA; see fig. 17), etc.

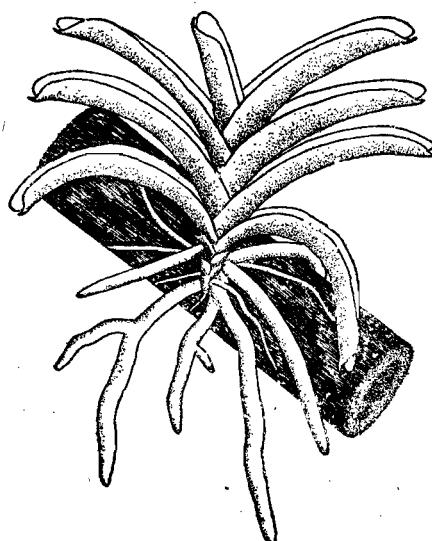

FIG. 57. Epiphytic roots of *Vanda* (an orchid).

lop certain kinds of adventitious roots which are soft, light, spongy and colourless. They usually develop above the level of water and serve to store up air. Thus they facilitate respiration.

10. Epiphytic Roots (fig. 57). There are certain plants, commonly orchids, which grow on branches of trees. Such plants are known as **epiphytes** (*epi*, upon; *phyta*, plants). They never suck the supporting plant as do parasites. So instead of sucking roots they develop special kinds of aerial roots which hang freely in the air. Each hanging root is surrounded by a spongy tissue, called **velamen**. With the help of this velamen the hanging root absorbs moisture from the surrounding air. *Vanda* (B. RASNA), an epiphytic orchid, is a common example.

11. Assimilatory Roots. Branches of *Tinospora* (B. GULANCHI; H. GURCHA) climbing on neighbouring trees produce long, slender, hanging roots which develop chlorophyll and turn green in colour. These green roots are the assimilatory roots. They carry on carbon-assimilation, i.e. they absorb carbon dioxide from the air and manufacture carbohydrate food. The

9. Respiratory Roots (fig. 56B). In *Jussiaea* (B. KESSRA), an aquatic plant, the floating branches deve-

hanging roots of epiphytic orchids (fig. 57) also often turn green in colour. The submerged roots of water chestnut (fig. 58) are green in colour and act as assimilatory roots.

Functions and Adaptations of the Root. The root performs manifold functions—*mechanical* such as **fixation**, and *physiological* such as **absorption**, **conduction** and **storage**. These are the normal functions of the root. Roots also have specialized functions and they adapt themselves accordingly. All these functions and adaptations have been discussed in detail in connexion with

the modified roots (see pp. 31-5).

(1) **Fixation.** The mechanical function the root performs is the fixation of the plant to the soil. The main root goes deep into the soil and the lateral roots spread out in different directions; so the root system as a whole firmly anchors the plant. In monocotyledons this anchorage is afforded by the fibrous roots.

(2) **Absorption.** The most important physiological function is the absorption of water and raw food material from the soil. This is done with the help of root-hairs which develop in a cluster at a little distance behind the root-cap. These root-hairs adhere to the soil particles and absorb water and soluble salts from them.

(3) **Conduction.** The root is concerned in the conduction of water and mineral salts, sending them upwards into the stem and ultimately into the leaf.

(4) **Storage.** There is a certain amount of food stored in the root, particularly in its mature region. As the root grows this stored food is utilized.

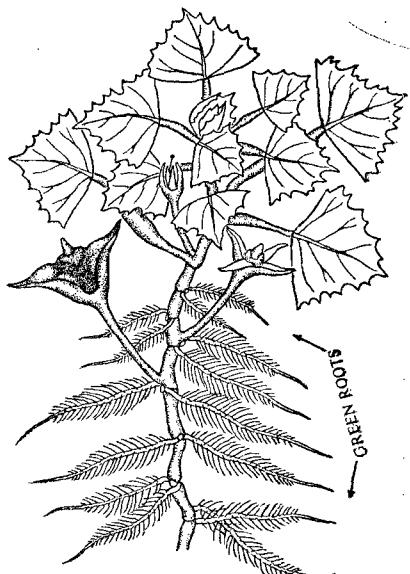

FIG. 58. Assimilatory (green) roots of water chestnut (*Trapa*).

It may be summarized that anchorage, conduction and storage are carried on normally by the older portions of the root system, and absorption by the root-hairs and tender portions.

CHAPTER 5 *The Stem*

Characteristics of the Stem. The stem is the ascending organ of the plant, and is the direct prolongation of the plumule. It normally bears leaves, branches and flowers, and when young, it is green in colour. The growing apex is covered over and protected by a number of tiny leaves which arch over it (see fig. 59B). The stem often bears multicellular hairs of different kinds; it branches exogenously; and it is provided with nodes and internodes which may not be distinct in all cases. Leaves and branches normally develop from the nodes. When the stem or the branch ends in a vegetative bud it continues to grow upwards or sideways. If, however, it ends in a floral bud the growth ceases.

Nodes and internodes. The place on the stem or branch where one or more leaves arise is known as the node, and the space between two successive nodes is called the internode. Sometimes nodes and internodes are very conspicuous, as in bamboos and grasses ; in others they are not always clearly marked.

THE BUD

A bud (fig. 59) is a young undeveloped shoot consisting of a short stem and a number of tender leaves arching over the growing apex. In the bud the internodes have not yet developed and the leaves remain closely crowded together forming a compact structure. The lower leaves of the bud are older and larger than those higher. The bud that grows in the axil of a leaf (**axillary bud**) or at the apex of a stem or branch (**terminal bud**) is regarded as *normal*. The bud that arises in any other part of the plant body is regarded as *adventitious*. Adventitious buds may be *radical buds* growing on the root, as in sweet potato (see fig. 50) or *foliar buds* growing on the leaf, as in sprout leaf plant (fig. 60) and elephant ear plant (fig. 61), or *cauline buds* growing on any part of the stem or branch. When a stem or branch is cut, adventitious buds often appear all round the cut surface.

Buds that develop into branches with leaves are called **vegetative buds** and those that develop into flowers are called **floral buds**.

Protection of the Bud.
The bud is protected in various ways against sun, rain, fungi and insects. (1) The young leaves of a bud overlap one another giving protection to themselves as well as to the growing apex. (2) It may be covered by hairs; glandular hairs are very effective in this respect. (3) It may be enclosed by some dry scales, called **bud-scales**, as in banyan, jack, etc. (4) There may be a coating of wax or cutin.

Modification of the Bud. Vegetative buds may be modified into tendrils (see fig. 7), as in passion-flower and vine, or into thorns

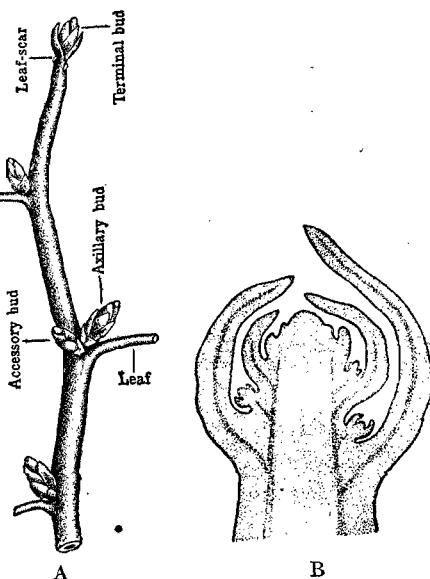

FIG. 59. A, a branch showing position of buds ; B, a bud in longi-section.

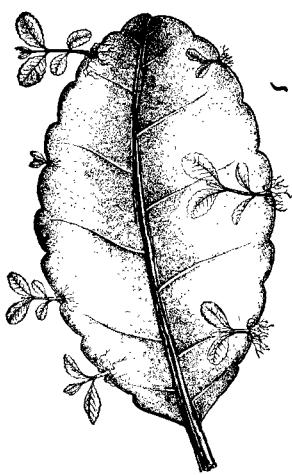

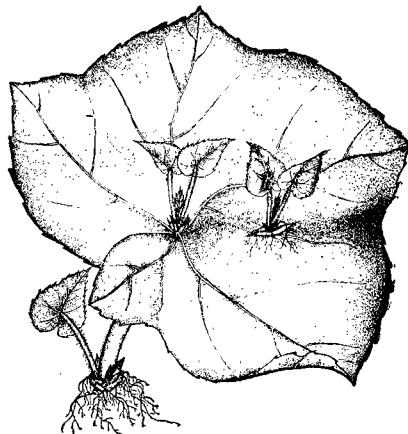

FIG. 60. Foliar buds and adventitious roots of sprout leaf plant (*Bryophyllum*). FIG. 61. The same of elephant ear plant (*Begonia*).

(see fig. 73), as in *Duranta* (B. DURANTA-KANTA ; H. NIL-KANTA), *Carissa* (B. KARANJA ; H. KARONDA), wood-apple, etc. Sometimes these may become modified into special reproductive bodies, known as **bulbils** (see figs. 361-4).

FORMS OF STEMS

There is a variety of stem structures adapted to perform diverse functions. They may be aerial or underground. Aerial stems may be erect, rigid and strong, holding themselves in an upright position ; while there are some too weak to support themselves in such a position. They either trail along the ground or climb neighbouring plants or objects.

1. Erect or Strong Stems. The unbranched, erect, cylindrical and stout stem, marked with scars of fallen leaves, is called **caudex**, as in palms. The jointed stem with solid nodes and hollow internodes is called **culm**, as in bamboo. Some herbaceous plants, particularly monocotyledons, normally have no aerial stem. At the time of flowering, however, the underground stem produces through the rosette of radical leaves an erect, unbranched, aerial shoot bearing either a single flower or a cluster of flowers on the top ; such a flowering shoot is called **scape**. The scape dries up as soon as the flowering season is over. Common examples are tuberose, onion, American aloe, aroids, etc. The scape is leafless or almost so.

2. Weak Stems. It is evident that a weak stem cannot stand upright. When such a stem lies flat on the ground, e.g. wood-sorrel (see fig. 66), Indian pennywort (see fig. 359), dog grass, etc., it is said to be (1) **prostrate**. When such a stem after trailing for some distance lifts its head, e.g. *Tridax* (see fig. 455), it is said to be (2) **decumbent**. When the stem is much branched and the branches spread out on the ground on all sides, e.g. *Boerhaavia* (B. PUNARNAVA ; H. THIKRI or SANT), it is said to be (3) **diffuse**. A weak stem creeping on the ground and rooting at the nodes, e.g. sweet potato (see fig. 50), is said to be (4) **creeping**. When the stem bodily twines round a support without any special organ of attachment, e.g. *Clitoria* (B. APARAJITA ; H. APARAJIT), *Abrus* (B. KUNCH ; H. RATTI), etc., it is said to be (5) **twining**. Some twiners by nature move clockwise, while others anticlockwise. When the stem attaches itself to a nearby support by

means of some special device, e.g. betel, cane, rose, pea, passion-flower, gourd, etc., it is said to be (6) **climbing** (see pp. 3-6).

MODIFICATIONS OF STEMS

Stems or branches of certain plants are modified into various shapes to perform special functions. The special functions are: (a) perennation, i.e. surviving from year to year through bad seasons by certain underground stems; (b) vegetative propagation by certain horizontal sub-aerial branches spreading out in different directions; and (c) highly specialized functions of varied nature by certain metamorphosed aerial organs. Thus in response to the above functions stems undergo modifications into different and distinct forms, each to meet a special need, as follows.

i. Underground Modifications of Stems. For the purpose of perennation stems of certain plants develop underground and lodge there permanently, lying in a dormant, leafless condition for some time and then giving off aerial shoots annually under favourable conditions. They are always thick and fleshy, having a heavy deposit of reserve food material in them. Developing underground they often look like roots but are readily distinguished from them by the presence of (a) nodes and internodes, (b) scale-leaves, and (c) buds (axillary and terminal). The main function of this group of modified stems is, as already stated, (a) perennation; but they also (b) store up food material and (c) propagate, i.e. multiply plants vegetatively. The various types met with in this group are as follows:

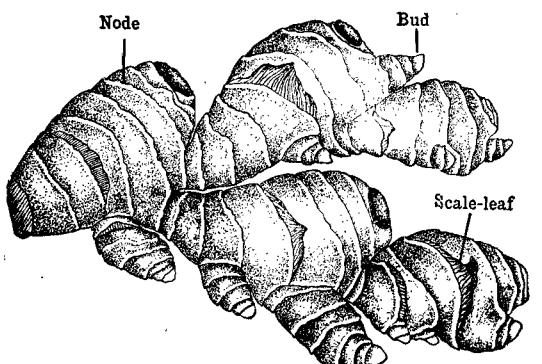

FIG. 62.
Rhizome
of ginger.

(1) **Rhizome** (fig. 62). The rhizome is a thickened, prostrate, underground stem provided with distinct nodes and internodes,

scaly leaves at the nodes, a bud in the axil of each such leaf, and a terminal bud. Some slender adventitious roots are given off from its lower side. It may be branched or unbranched. Most of the time it remains underground in a dormant condition but after a few showers of rain the terminal bud and some of the axillary buds grow up into long or short leafy aerial shoots which again die down after a few months. Common examples are seen in *Canna*, ginger, turmeric, arrowroot, water lily, ferns, etc. Its direction is normally horizontal, but sometimes it grows in the vertical direction (**rootstock**), as in *Alocasia* (B. MAN-KACHU ; H. MAN-KANDA).

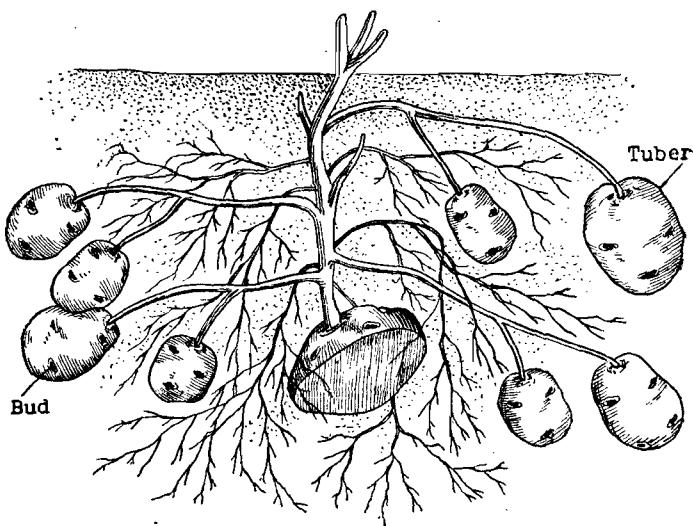

FIG. 63. Tubers of potato.

(2) **Tuber** (fig. 63). This is the swollen end of a special underground branch (tuber means a swelling). The underground branch arises from the axil of a lower leaf, grows horizontally outwards and ultimately swells up at the apex due to accumulation of a large quantity of food there, and becomes almost spherical, e.g. potato. It has on its surface a number of 'eyes' or buds which grow up into new plants. Adventitious roots are usually absent from a tuber.

(3) **Bulb** (fig. 64). This is another underground modified shoot (really a single, often large, terminal bud) consisting of a shortened convex or slightly conical stem, a terminal bud and numerous scale-leaves (which are the swollen bases of foliage

leaves), with a cluster of fibrous roots at the base. The scale-leaves, often simply called scales, commonly occur surrounding

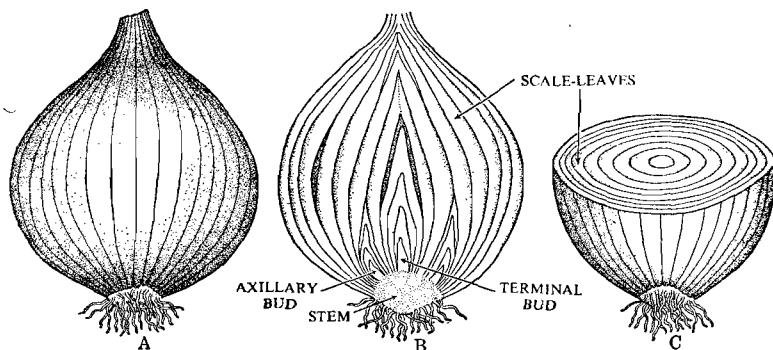

FIG. 64. Bulb of onion. A, an entire bulb with adventitious roots, and outer dry scale-leaves with distinct veins; B, bulb cut longitudinally; and C, bulb cut transversely.

the short stem in a concentric manner (tunicated bulb), rarely they are narrow and just overlap each other (scaly bulb). The inner scales of the bulb are usually fleshy storing water and food, while the outer ones dry giving protection. The terminal bud grows into the aerial shoot ; some of the axillary buds also do the same and finally form daughter bulbs. Common examples are onion, garlic, tuberose, most lilies, etc.

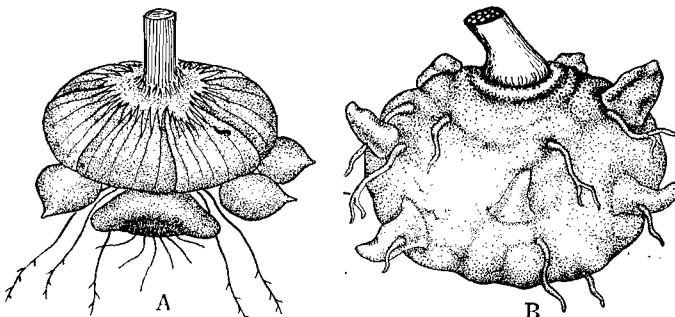

FIG. 65. A, corm of *Gladiolus*; B, the same of *Amorphophallus* (B. OL; H. KANDA).

(4) **Corm** (fig. 65). This is a condensed form of rhizome and consists of a stout, solid, fleshy, underground stem growing in the vertical direction. It is more or less rounded in shape or often somewhat flattened from top to bottom. It contains a heavy deposit of food material and often grows to a considerable size. It bears one or more buds in the axils of scale-leaves, and some

of these buds grow up into daughter corms. Adventitious roots normally develop from the base but sometimes also from the sides. Corm is found in *Amorphophallus* (B. OL ; H. KANDA), taro (B. KACHU ; H. KACHALU), *Gladiolus*, saffron, etc.

2. Sub-aerial Modifications of Stems. For the purpose of vegetative propagation some of the lower buds of the stem in certain plants grow out into long or short, slender or stout, lateral branches which according to their origin, nature and mode of propagation have received different names. These are as follows:

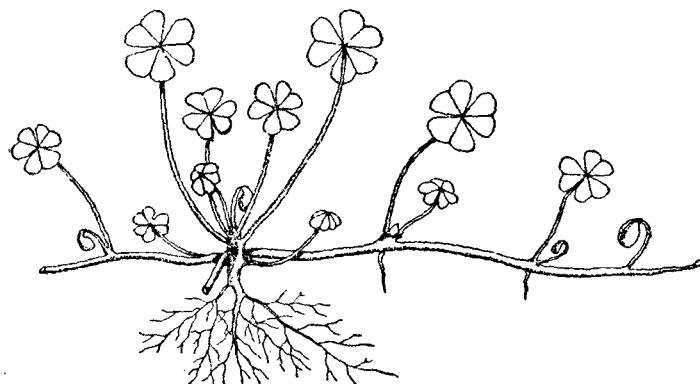

FIG. 66. Runner of wood-sorrel (*Oxalis*).

(i) **Runner** (fig. 66). This is a slender, prostrate branch with long internodes, creeping on the ground and rooting at the nodes. The runner arises as an axillary bud and creeps some distance away from the mother plant,

then strikes roots and grows into a new plant. Many such runners are often produced by the mother plant and they spread out on the ground on all sides. Examples are seen in wood-sorrel (fig. 66), Indian pennywort (see fig. 359), *Tarsilea* (B. SUSHNISAK), strawberry, wild strawberry, etc.

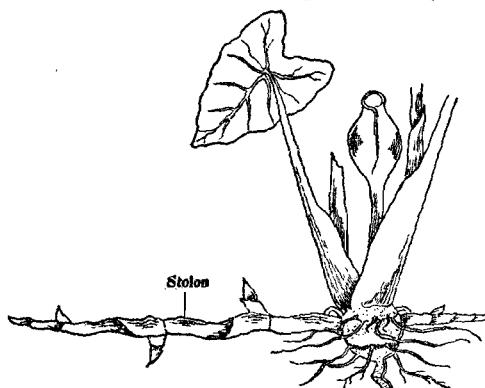

FIG. 67. Stolon of taro (*Colocasia*). •

(2) **Stolon** (fig. 67). This is a slender lateral branch which originates from an underground stem and grows horizontally outwards for a shorter or longer distance. It is often provided with nodes and internodes. The stolon resembles a runner but it is subterranean, while the runner is sub-aerial. Examples are seen in taro (B. KACHU; H. KACHALU), arrowroot, passion-flower, some jasmines, sandal rose, etc.

(3) **Offset** (fig. 68). Like the runner this originates in the axil of a leaf as a short, more or less thickened, horizontal branch. It elongates to some extent only. The apex then turns up and produces a tuft of leaves above and a cluster of roots below.

The offset often breaks away from the mother plant into

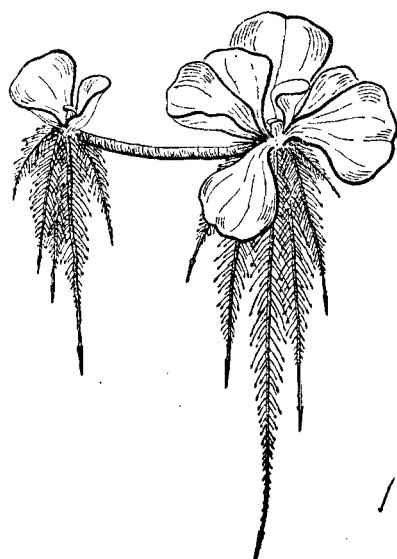

FIG. 68. Offset of water lettuce
(*Pistia*).

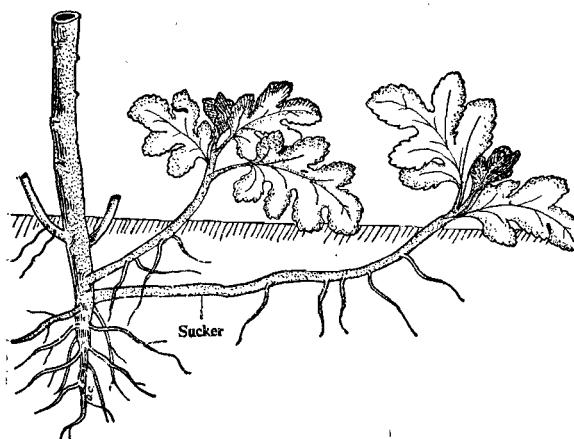

FIG. 69. Suckers of *Chrysanthemum*.

an independent one. Common examples are water lettuce (fig. 68) and water hyacinth (see fig. 82). An offset is shorter and

stouter than a runner, and is found only in the rosette type of plants.

(4) **Sucker** (fig. 69). Like the stolon the sucker is also a lateral branch developing from the underground part of the stem. But it grows obliquely upwards and gives rise to a leafy shoot or a new plant. It may be a slender branch, or a short stout one, as in banana. A sucker is always much shorter than a stolon. The sucker strikes roots at the base either before it separates from the mother plant or soon after. Examples are seen in *Chrysanthemum*, rose, mint (B. PUDINA; H. PODINA), pineapple, banana, dagger plant, etc.

3. Aerial Modifications : Metamorphoses. Vegetative and floral buds which would normally develop into branches and flowers, often undergo extreme degrees of modification (metamorphosis) in certain plants for definite purposes. Metamorphosed organs are stem-tendril for climbing, thorn for protection, phylloclade for food manufacture, and bulbil for vegetative reproduction.

(1) **Stem-tendril** (figs. 70-2). This is a thin, wiry, leafless, spirally coiled branch, formed only in some climbers and used by

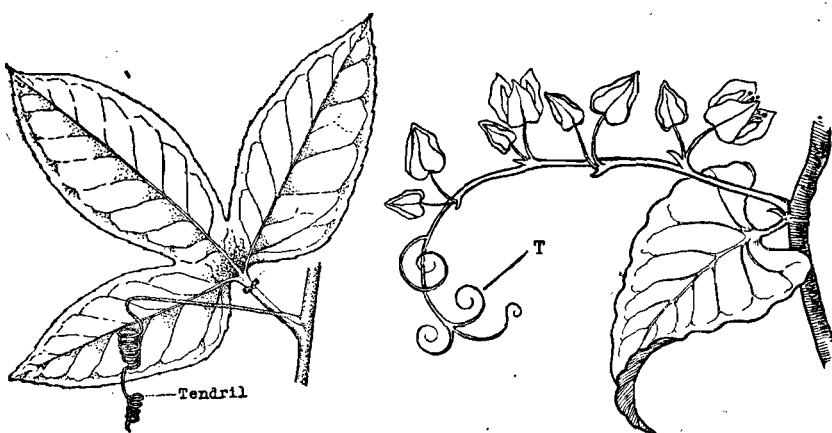

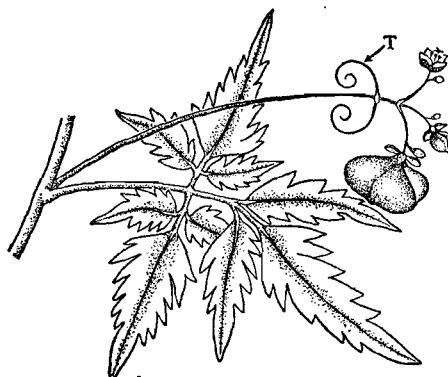

FIG. 70

FIG. 70. Tendril of passion-flower (*Passiflora*). FIG. 71. Tendrils of Sandwich Island climber (*Antigonon*). T, a tendril.

them as a climbing organ. The tendril coming in contact with any neighbouring object coils round it and helps such plants

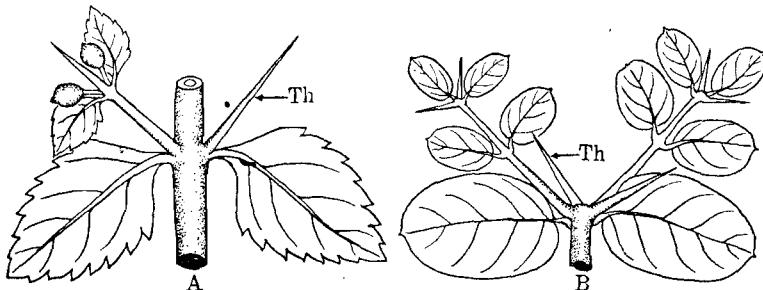

to climb. The stem-tendril may be a modification of an axillary bud, as in passion-flower (fig. 70), or of a terminal bud,

FIG. 72.
Tendrils of balloon vine
(*Cardiospermum*).
T, a tendril.

as in vine, or even of a flower, as in balloon vine (fig. 72) and Sandwich Island climber (fig. 71).

(2) **Thorn** (fig. 73). The thorn is a hard, often straight and pointed structure. It may be a modification of an axillary bud, as in *Duranta*, lemon, wood-apple, etc., or of a terminal bud, as

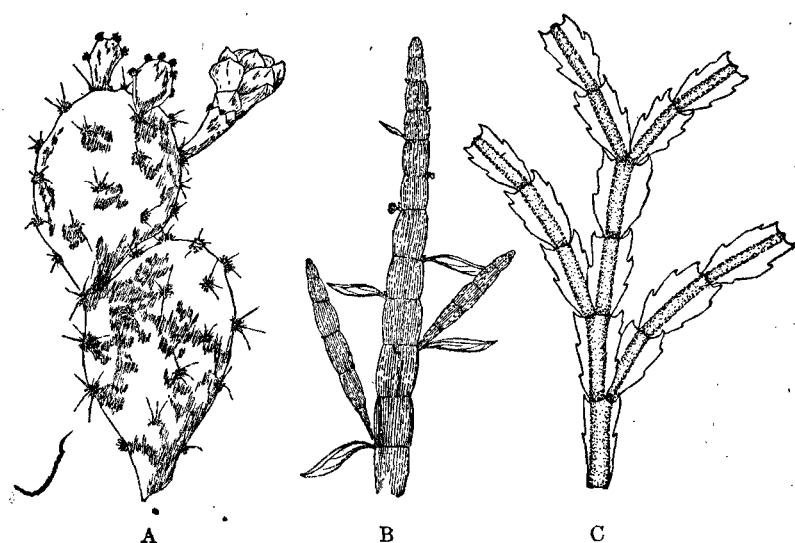

Thorns. FIG. 73. A, thorns of *Duranta*; B, thorns of *Carissa*.
Th, thorn.

in *Carissa* (B. KARANJA; H. & P. KARONDA). The thorn may sometimes be branched, and may even bear leaves, flowers and fruits. The thorn is a defensive organ meant to keep off browsing animals. Sometimes, as in glory of the garden (see fig. 2) it is also used as a climbing organ.

(3) **Phylloclade** (fig. 74). Phylloclade is a green, commonly flattened or sometimes rounded stem or branch which performs

the functions of leaves, the latter being either feebly developed or modified into spines. Phylloclade is seen in most cacti,

Phylloclades. FIG. 74. A, prickly pear (*Opuntia*); B, coccoloba; C, *Epiphyllum*.

e.g. prickly pear, night-blooming cacti, *Epiphyllum*, etc. It is also seen in *Casuarina* (B. & H. JHAU), *Euphorbia* (B. & H. SJ), etc. The phylloclade of one internode is spoken of as the **cladode** (fig. 75), as in *Asparagus* (B. SATAMULI ; H. SATAWAR). Duckweed (*Lemna*; see fig. 39) is another common example of cladode.

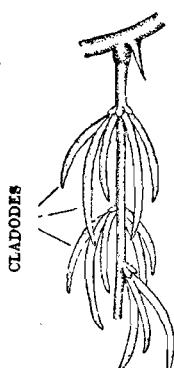

FIG. 75. Cladodes of *Asparagus*.

(4) **Bulbil** (see figs. 361-4). Bulbil is a special multicellular reproductive body, i.e. it is essentially meant for the reproduction of the plant. It may be the modification of a vegetative bud or of a floral bud. In any case it sheds from the mother plant and grows up into a new independent one. Bulbils are seen in *Globba*, wild yam (B. GACHH-ALOO ; H. ZAMIN-KHAND), American aloe, wood-sorrel, etc.

Modifications of Stems

Underground	Sub-aerial	Aerial (Metamorphoses)
—rhizome, e.g. ginger.	—runner, e.g. wood-sorrel.	—tendril, e.g. passion-flower and vine.
—tuber, e.g. potato.	—stolon, e.g. taro.	—thorn, e.g. <i>Duranta</i> .

		—bulbil, e.g. <i>Globba</i> and wild yam.

BRANCHING

The mode of arrangement of the branches on the stem is known as **branching**. There are two principal types of branching, viz. **lateral** and **dichotomous**.

A. LATERAL BRANCHING

When the branches are produced laterally, that is, from the sides of the main stem, the branching is called **lateral**. The lateral branching may be **racemose** or indefinite and **cymose** or definite.

1. **Racemose Type** (fig. 76). Here the growth of the main stem is indefinite, that is, it continues to grow indefinitely by the terminal bud and give off branches laterally in acropetal succession.

FIG. 76

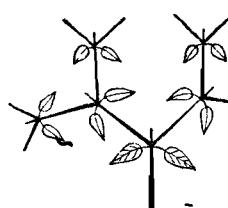

FIG. 77

A

B

FIG. 78

Branching. FIG. 76. Racemose type. FIG. 77. True (biparous) cyme.
FIG. 78. Uniparous cyme; A, scorpioid; B, helicoid.

sion, i.e. the lower branches are older and longer than the upper ones, as in *Casuarina* (B. & H. JHAU), mast tree (B. DEBDARU ; H. DEVADARU or ASHOK), etc. As a result of this branching the plant takes on a conical or pyramidal shape.

2. **Cymose Type**. Here the growth of the main stem is definite, that is, the terminal bud does not continue to grow, but lower

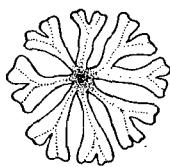

down, the main stem produces one or more lateral branches which grow more vigorously than the terminal one. The process may be repeated. As a result of cymose branching the plant spreads out above, and becomes more or less dome-shaped. Cymose branching may be of the following kinds:

(1) **Biparous Cyme** (fig. 77). If, in the cymose branching, two lateral axes develop at a time, it is called biparous or true cyme, as in mistletoe (see fig. 17), four o'clock plant, *Carissa* (B. KARANJA ; H. KARONDA—see fig. 73B), pagoda tree (B. KATCHAMPA ; H. GOLAINCHI), etc.

(2) **Uniparous Cyme**. If, in the cymose type, only one lateral branch is produced at a time, the branching is said to be uniparous (i.e. having but one axis at a time). It has two distinct forms: (a) **helicoid** or one-sided cyme (fig. 78B), when successive lateral branches develop on the same side, forming a sort of helix, as in *Saraca* (B. ASOK ; H. SEETA ASHOK), and (b) **scorpioid** or alternate-sided cyme (fig. 78A), when successive lateral branches develop on alternate sides, forming a zig-zag, as in vine, wild vine, *Cissus quadrangularis* (B. & H. HARHJORA), etc. In them the apparent or false axis is a succession of lateral axes.

B. DICHOTOMOUS BRANCHING

When the terminal bud bifurcates, that is, divides into two, producing two branches in a forked manner, the branching is termed dichotomous. Dichotomous branching is common among the 'flowerless' plants, as in *Riccia* (fig. 79), *Marchantia* (see fig. IVB), etc. Among the 'flowering' plants examples are seen in *Hyphaene* (a palm), screw pine (B. KETUCKY ; H. KEORA), etc.

Dichotomous Branching.
FIG. 79. *Riccia*.

FUNCTIONS OF THE STEM

1. **Bearing Leaves and Flowers.** The stem and the branches bear leaves and flowers, often numerous, and spread them out on all sides for proper functioning—the leaves to get the adequate amount of sunlight for manufacture of food, and the flowers to attract insects from a distance for pollination and reproduction.

2. **Conduction.** The stem *conducts* water and dissolved mineral salts from the root to the leaf, and prepared food material from

the leaf to the different parts of the plant body, particularly to the storage organs and the growing regions.

3. Support. The main stem acts as a sort of pillar *supporting* the branches which often spread out in different directions to push forward the leaves and the flowers.

4. Storage. The stem also serves as a *storehouse* of food material. This is particularly true of the underground modified stems (see figs. 62-5) which are specially constructed for food storage, as in ginger, potato, onion and *Amorphophallus* (B. OL ; H. KANDA). Fleshy stems of cacti and spurge (*Euphorbia*) always store a large quantity of water.

5. Food Manufacture. The young shoot, when green in colour, *manufactures* food material in the presence of sunlight with the help of chloroplasts contained in it.

In addition to those stated above, metamorphosed stems carry on specialized functions ; for example, the tendril helps a plant to climb, and the thorn protects it against grazing animals, and so on (see pp. 44-6).

CHAPTER 6 *The Leaf*

The leaf may be regarded as the flattened, lateral outgrowth of the stem or the branch, developing from a node and having a bud in its axil. It is normally green in colour and is regarded as the most important vegetative organ of the plant since food material is prepared in it. Leaves always develop in an *acropetal order* and are *exogenous* in origin.

Parts of a Leaf (fig. 80). A typical leaf consists of the following parts, each with its own function.

(1) **Leaf-base** is the part attached to the stem. In many plants the leaf-base expands into a **sheath** which partially or wholly clasps the stem. This *sheathing* leaf-base is of frequent occurrence among monocotyledons, and is well developed in

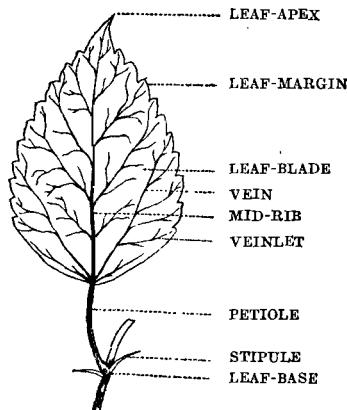

FIG. 80. Parts of a leaf.

grasses ; in the banana plant the so-called stem is made up of leaf-sheaths. In dicotyledons, on the other hand, the leaf-base usually bears two lateral outgrowths, known as the **stipules**. In some leaves such as those of gram, pea, tamarind, sensitive plant, rain tree, gold mohur, butterfly pea (*Clitoria* ; *B. APARAJITA* ; *H. APARAJIT*), etc., the leaf-base is swollen, and then it is known as the **pulvinus** (fig. 81).

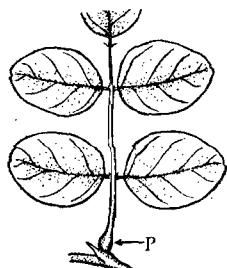

FIG. 81

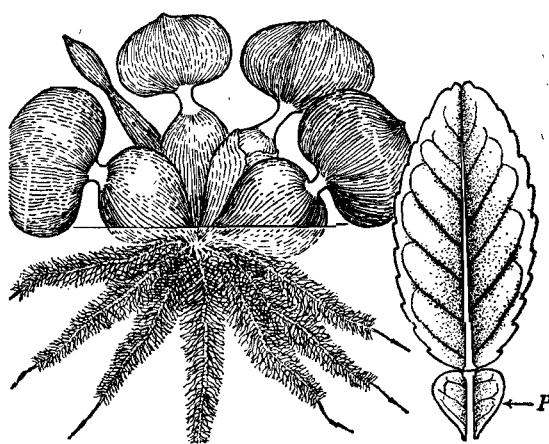

FIG. 82

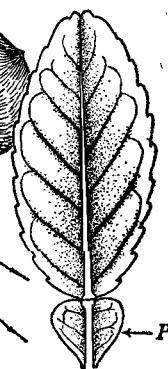

FIG. 83

FIG. 81. *Clitoria* leaf showing pulvinus (P). FIG. 82. Water hyacinth leaf showing bulbous petiole. FIG. 83. Pummelo leaf showing winged petiole (P).

(2) **Petiole** is the stalk of the leaf. A long petiole pushes out the leaf-blade and thus helps it to secure more sunlight. When the petiole is absent the leaf is said to be sessile ; and when present it is said to be **petiolate** or stalked. In many plants the petiole shows certain peculiarities. Thus in water hyacinth (fig. 82) it swells into a spongy bulb, often called pseudo-bulb, containing innumerable air-chambers for facility of floating ; while in orange, pummelo or shaddock, etc., it becomes winged (fig. 83). In Australian *Acacia* (see fig. 119) it is modified into a flattened sickle-shaped lamina or blade, called phyllode. In *Clematis* (see fig. 10) the petiole is tendrillar in nature.

(3) **Leaf-blade** or **lamina** is the green, expanded portion. A strong vein, known as the mid-rib, runs centrally through the leaf-blade from its base to the apex ; this produces thinner lateral **veins** which in their turn give rise to still thinner veins or veinlets. The lamina is the most important part of the leaf since this is the seat of food-manufacture for the entire plant.

Duration of the Leaf. The leaf varies in its duration. It may fall off soon after it appears ; then it is said to be (1) **caducous** ; if it lasts one season, usually falling off in winter, it is (2) **deciduous** or **annual** ; and if it persists for more than one season, usually lasting a number of years, it is (3) **persistent** or **evergreen**.

Some Descriptive Terms. (1) **Dorsiventral Leaf.** When the leaf is flat, with the blade placed horizontally, showing distinct upper surface and lower surface, it is said to be dorsiventral (*dorsum*, back ; *venter*, belly or front), as in most dicotyledons. A dorsiventral leaf is more strongly illuminated on the upper surface than on the lower and, therefore, this surface is deeper green in colour than the lower. In internal structure also there is a good deal of difference between the two sides (see fig. 312). (2) **Isobilateral Leaf.** When the leaf is directed vertically upwards, as in most monocotyledons, it is said to be isobilateral (*isos*, equal ; *bi*, two ; *lateris*, side). An isobilateral leaf is equally illuminated on both the surfaces and, therefore, the leaf is uniformly green and its internal structure is also uniform from one side to the other (see fig. 313). (3) **Centric Leaf.** When the leaf is more or less cylindrical and directed upwards or downwards, as in pine, onion, etc., the leaf is said to be centric. A centric leaf is equally illuminated on all sides and, therefore, it is evenly green.

STIPULES.

Stipules are the lateral appendages of the leaf borne at its base. These are often green, but sometimes they have a withered look. They may remain as long as the lamina persists (**persistent**) or may fall off soon after the lamina unfolds (**deciduous**) or sometimes they may shed even before the lamina unfolds (**caducous**). Their function is to protect the young leaves in the bud, and when green they manufacture food material like leaves. When stipules are present the leaf is said to be **stipulate**, and when absent **exstipulate**. Sometimes, as in *Clitoria* (B. APARAJITA ; H. APARAJIT), a small stipule is present at the base of each leaflet. Such a small stipule is otherwise known as a **stipel**.

Kinds of Stipules. According to their shape, position, colour and size, stipules are of the following kinds :

(1) **Free Lateral Stipules** (fig. 80). These are two free stipules,

usually small and green in colour, borne on the two sides of the leaf-base, as in China rose, cotton, etc.

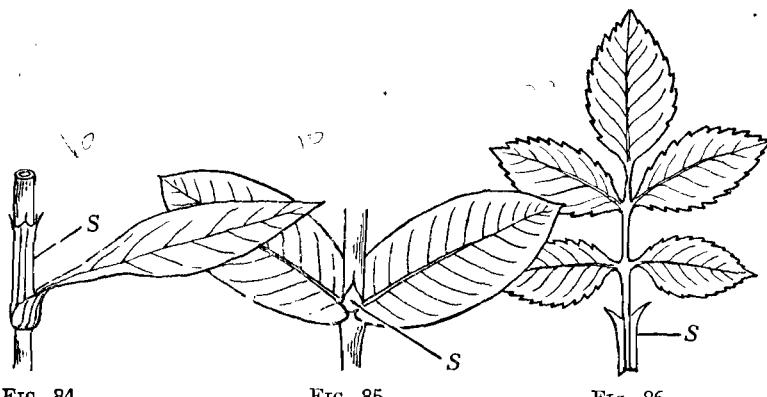

FIG. 84

FIG. 85

FIG. 86

Kinds of Stipules. FIG. 84. Ochreate stipule (*S*) of *Polygonum*.
FIG. 85. Interpetiolar stipule (*S*) of *Ixora*. FIG. 86. Adnate
stipule (*S*) of rose.

(2) **Scaly Stipules.** These are small dry scales, usually two in number, borne on the two sides of the leaf-base, as in Indian telegraph plant.

(3) **Adnate Stipules** (fig. 86). These are the two lateral stipules that grow along the petiole up to a certain height, adhering to it and making it somewhat winged in appearance, as in rose, groundnut, strawberry and lupin.

(4) **Interpetiolar Stipules** (fig. 85). These are the two stipules that lie between the petioles of opposite or whorled leaves, thus alternating with the latter. These are seen in *Ixora* (B. RANGAN), *Anthocephalus* (B. & H. KADAM), etc.

(5) **Ochreate Stipules** (fig. 84). These form a hollow tube encircling the stem from the node up to a certain height of the internode in front of the petiole, as in *Polygonum*.

(6) **Foliaceous Stipules** (see figs. 113-14). These are two large, green, leafy structures, as in pea and wild pea.

(7) **Bud-scales.** These are scaly stipules which enclose and protect the vegetative buds, and fall off as soon as the leaves unfold. They are seen in banyan, jack, *Magnolia*, etc.

Modified Forms of Stipules. Stipules are sometimes modified into **spines** and **tendrils**, and perform functions peculiar to these two structures. (1) **Spinous Stipules** (fig. 87). In some plants, as

in gum tree, Indian plum, sensitive plant, caper, etc., the stipules become modified into two sharp pointed structures known as spines, one on each side of the leaf-base. Such spinous stipules

FIG. 87. Spinous stipules of Indian plum (*Zizyphus*).*

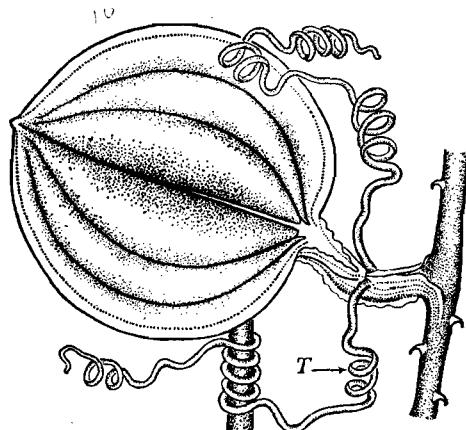

FIG. 88. Tendrillar stipules (T) of *Smilax*.

give protection to the leaf against the attack of herbivorous animals. (2) **Tendrillar Stipules** (fig. 88). In *Smilax* (B. KUMARIKA; H. CHOBCHINI) the stipules become modified into two strong closely-coiled tendrils, one on each side of the petiole. These tendrillar stipules help the plant to climb neighbouring shrubs and trees.

LEAF - BLADE

Apex of the leaf (fig. 89.) The apex of the leaf is said to be (A) **obtuse**, when it is rounded, as in banyan ; (B) **acute**, when it is pointed in the form of an acute angle, but not stiff, as in China rose ; (C) **acuminate** or **caudate**, when it is drawn out into a long slender tail, as in peepul and lady's umbrella (*Holmskioldia*) ; (D) **cuspidate**, when it ends in a long rigid sharp (spiny) point, as in date-palm, screwpine and pineapple ; (E) **retuse**, when the obtuse or truncate apex is furnished with a shallow notch, as in water lettuce (*Pistia*) ; (F) **emarginate**, when the apex is provided with a deep notch, as in *Bauhinia* (B. KANCHAN ; H. KANCHAR) and wood-sorrel (*Oxalis*) ; (G) **mucronate**, when the rounded apex abruptly ends in a short point, as in *Ixora* (B. RANGAN ; H. GOTAGANDHAL) ; and (H) **cirrhose** (*cirrus*, a tendril or a curl), when it ends in a tendril, as in glory lily, or in a slender curled thread-like appendage, as in banana.

Margin of the Leaf. The margin of the leaf may be (1) **entire**, i.e. even and smooth, as in mango, jack, banyan, etc. ; (2) **sinuate**, i.e. undulating, as in mast tree (B. DEBDARU ; H. ASHOK) and some garden crotons ; (3)

serrate, i.e. cut like the teeth of a saw and the teeth directed upwards, as in China rose, rose, margosa (B. & H. NIM or NIMBA), etc.; (4) **dentate**, i.e. the teeth directed outwards at right angles to the margin of the leaf, as in melon and water lily; (5) **crenate**, i.e. the teeth rounded, as in sprout

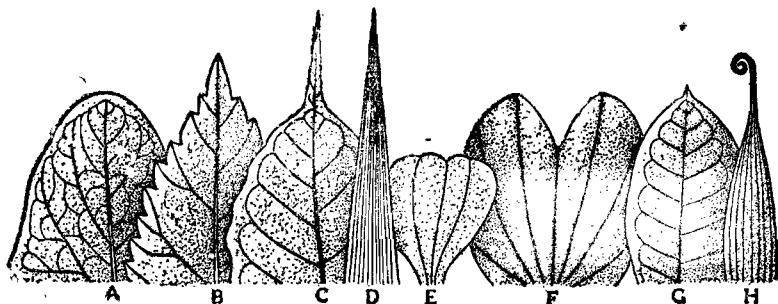

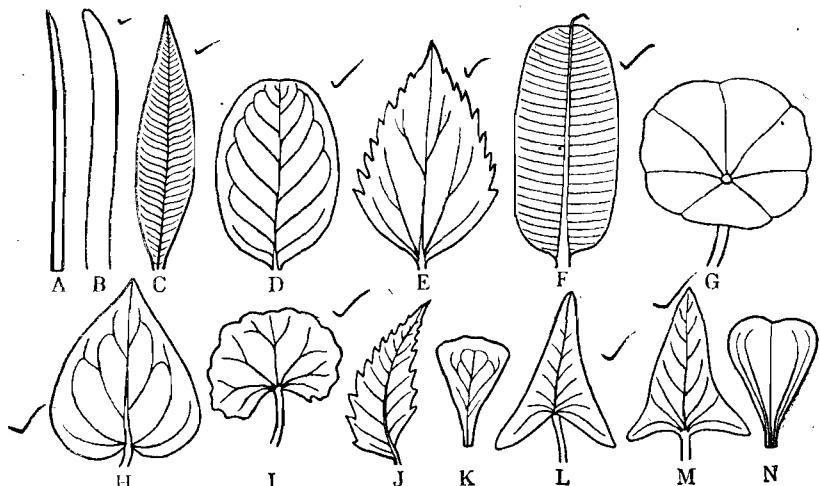

FIG. 89. Apex of the leaf. A, obtuse; B, acute; C, acuminate; D, cuspidate; E, retuse; F, emarginate; G, mucronate; and H, circinate.

leaf plant (*Bryophyllum*) and Indian pennywort; and (6) **spinous**, i.e. provided with spines, as in prickly poppy (*Argemone*).

Surface of the Leaf. The leaf is said to be (1) **glabrous**, when the surface of it is smooth and free from hairs or outgrowths of any kind; (2) **rough**, when the surface is somewhat harsh to touch; (3) **glutinous**, when the surface of it is covered with a sticky exudation, as in tobacco; (4) **glaucous**, when the surface is green and shining; (5) **spiny**, when it is provided with spines; and (6) **hairy**, when it is covered, densely or sparsely, with hairs.

Shape of the Leaf (fig. 90). (A) **Acicular**, when the leaf is long, narrow and

Shape of the Leaf. FIG. 90. A, acicular; B, linear; C, lanceolate; D, elliptical or oval; E, ovate; F, oblong; G, rotund or orbicular; H, cordate; I, reniform; J, oblique; K, spatulate; L, sagittate; M, hastate; and N, cuneate.

cylindrical, i.e. needle-shaped, as in pine, onion, etc. (B) **Linear**, when the leaf is long, narrow and flat, as in many grasses, tuberoose, *Vallisneria*, etc. (C) **Lanceolate**, when the shape is like that of a lance, as in bamboo, oleander, mast tree etc. (D) **Elliptical** or **oval**, when the leaf has more or less the shape of an ellipse, as in *Carissa*, periwinkle (*Vinca*), guava, roseapple, etc. (E) **Ovate**, when the blade is egg-shaped, i.e. broader at the base than at the apex, as in China rose, banyan, etc.; an inversely egg-shaped leaf is said to be **obovate**, as in country almond and jack. (F) **Oblong**, when the blade is wide and long, with the two margins running straight up, as in banana. (G) **Rotund** or **orbicular**, when the blade is more or less circular in outline, as in lotus, garden nasturtium, etc. (H) **Cordate**, when the blade is heart-shaped, as in betel, *Peperomia*, etc.; an inversely heart-shaped leaf is said to be **obcordate**, as in wood-sorrel. (I) **Reniform**, when the leaf is kidney-shaped, as in Indian pennywort. (J) **Oblique**, when the two halves of a leaf are unequal, as in *Begonia*; in margosa (B. & H. NIM) and Indian cork tree (B. & H. AKAS-NIM) and Persian lilac (B. CHORA-NIM) the leaflets are oblique. (K) **Spathulate**, when the shape is like that of a spatula, i.e. broad and somewhat rounded at the top and narrower at the base, as in sundew (*Drosera*) and *Ca'endula*. (L) **Sagittate**, when the blade is shaped like an arrow, as in arrowhead and some aroids. (M) **Hastate**, when the two lobes of a sagittate leaf are directed outwards, as in water bindweed (B. & H. KALMI-SAK) and *Typhonium* (B. GHET KACHU). (N) **Cuneate**, when the leaf is wedge-shaped, as in water lettuce (*Pistia*). (O) **Lyrate** (fig. 91), when the shape is like that of a lyre, i.e. with a large terminal lobe and some smaller lateral lobes, as in radish, mustard, etc. (P) **Pedate** (fig. 92), when the leaf is divided into a number of lobes which spread out like the claw of a bird, as in *Vitis pedata* (B. GOALE-LATA).

VENATION

Veins are rigid linear structures which arise from the petiole and the mid-rib and traverse the leaf-lamina in different directions; they are really vascular bundles and serve to distribute the water and dissolved mineral salts throughout the lamina and to carry away the prepared food from it; they also give the necessary amount of strength and rigidity to the thin, flat leaf-lamina.

The arrangement of the veins and the veinlets in the leaf-blade is known as **venation**. There are two principal types of

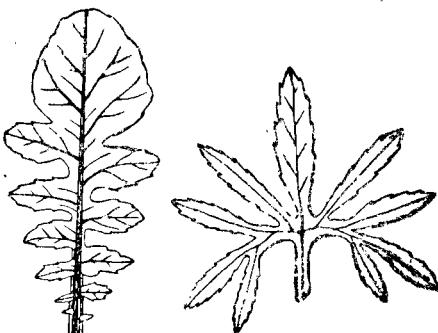

FIG. 91

FIG. 92

FIG. 91. Lyrate leaf of radish. FIG. 92.
Pedate leaf of *Vitis pedata*.

venation, viz. **reticulate**, when the veinlets are irregularly distributed, forming a network; and **parallel**, when the veins run

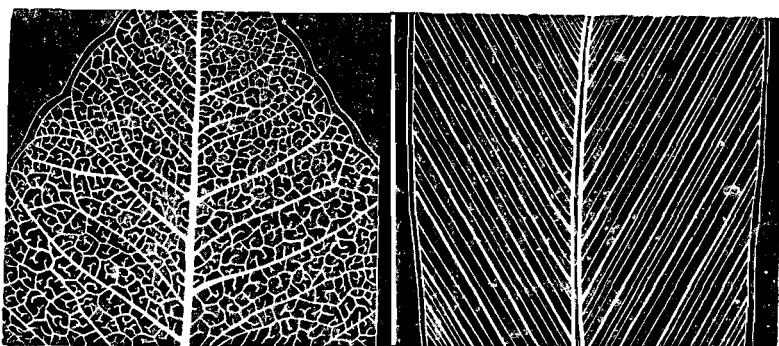

FIG. 93

FIG. 94

Systems of Veins. FIG. 93. Reticulate venation in a dicotyledonous leaf.
FIG. 94. Parallel venation in a monocotyledonous leaf.

parallel to each other. The former is characteristic of dicotyledons and the latter of monocotyledons. There are some exceptions in both.

I. RETICULATE VENATION

1. **Pinnate Venation.** In this type of venation there is a strong mid-rib; this gives off lateral veins which proceed towards the

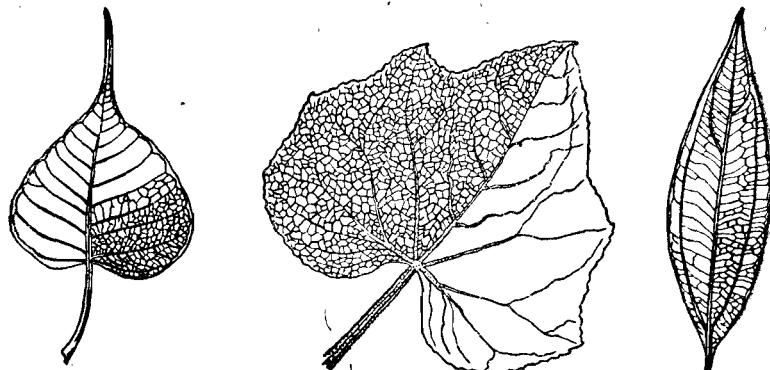

FIG. 95

FIG. 96

FIG. 97

Reticulate Venation. FIG. 95. Pinnate type in peepul leaf. FIG. 96. Palmate (divergent) type in cucumber leaf. FIG. 97. Palmate (convergent) type in bay leaf.

margin or apex of the leaf, like plumes in a feather (fig. 95). These produce still smaller veins and veinlets which pass in

all directions and become connected with one another, forming a network, as in guava, mango, jack, etc. This is a very common type of venation.

2. **Palmate Venation.** In this type there is a number of more or less equally strong ribs which arise from the tip of the petiole and proceed outwards or upwards. There are two forms: (1) in one the leaf possesses a number of strong veins that arise at the base of the leaf-blade and then diverge from one another towards the margin of the leaf, like the fingers from the palm (**divergent type**; fig. 96); these are then connected by a network of smaller veins, as in papaw, gourd, cucumber, castor, China rose, etc.; and (2) in the other the veins, instead of diverging from one another, run in a curved manner from the base of the blade to its apex (**convergent type**; fig. 97), as in cinnamon, camphor, Indian plum (B. KUL; H. BER), bay leaf (B. TEZPATA; H. TEZPAT), etc.

II. PARALLEL VENATION

1. **Pinnate Venation.** In this type of venation the leaf has a prominent mid-rib, and this gives off lateral veins which proceed parallel to each other towards the margin or apex of the leaf-blade (fig. 98), as in *Canna*, banana, ginger, turmeric, etc.

2. **Palmate Venation.** Two forms are also met with here: (1) the veins arise from the tip of the petiole and proceed (diverge) towards the margin of the leaf-blade in a more or less parallel

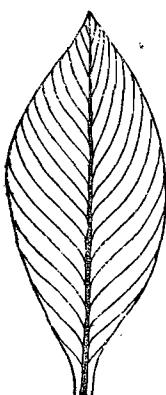

FIG. 98

FIG. 99

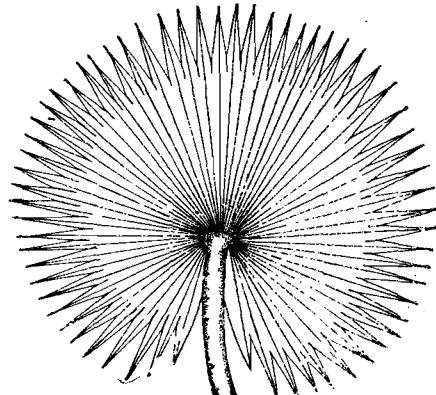

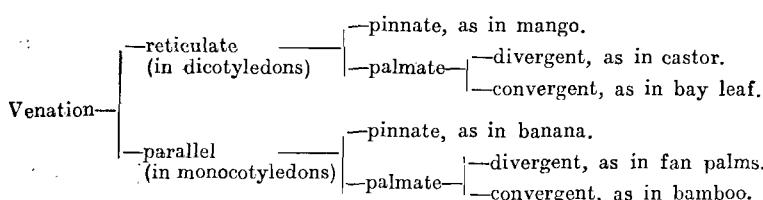

FIG. 100

Parallel Venation. FIG. 98. Pinnate type in *Canna* leaf. FIG. 99. Palmate (convergent) type in bamboo leaf. FIG. 100. Palmate (divergent) type in palmyra-palm leaf.

manner (**divergent type**; fig. 100), as in fan palms such as palmyra-palm; and (2) a number of more or less equally strong veins proceed from the base of the leaf-blade to its apex in a somewhat parallel direction (**convergent type**; fig. 99), as in water hyacinth, grasses, rice, bamboo, etc.

Functions of Veins. Veins are vascular bundles which ramify through the leaf-blade. Their main functions are conduction of water, salts and food, and strengthening of the leaf-blade.

(1) Veins distribute water and mineral or inorganic salts received from the stem throughout the leaf-blade, collect the prepared food material from the blade and send it to the stem, and thence to the storage organs and the growing regions.

(2) Veins form the skeleton of the leaf-blade and give rigidity to it so that it does not get torn or crumpled when a strong wind blows.

(3) Veins help the leaf-blade to keep flat so that its whole surface may be evenly illuminated by the sunlight.

COMPOUND LEAVES:

PINNATE AND PALMATE

Simple Leaf and Compound Leaf. A leaf is said to be **simple** when it consists of a single blade which may be entire or incised (and, therefore, lobed) to any depth, but not down to the mid-rib or the petiole; and a leaf is said to be **compound** when the incision of the leaf-blade goes down to the mid-rib (rachis) or to the petiole so that the leaf is broken up into a number of segments, called leaflets, these being free from one another, i.e. not connected by any lamina, and more or less distinctly jointed (articulated) at their base. A bud (axillary bud) is present in the axil of a simple or a compound leaf, but it is never present in the axil of the leaflet of a compound leaf. There are two types of compound leaves, viz. **pinnate** and **palmate**.

Compound Leaf and Branch. A compound leaf may be distinguished from a branch by the following facts: (1) a compound

leaf never bears a terminal bud ; whereas a branch always does so ; (2) a compound leaf, like a simple one, always bears a bud (axillary bud) in its axil, but itself does not arise in the axil of another leaf ; whereas a branch does not bear an axillary bud, but itself occupies the axillary position of a leaf—simple or compound—developing directly from the said bud ; (3) the

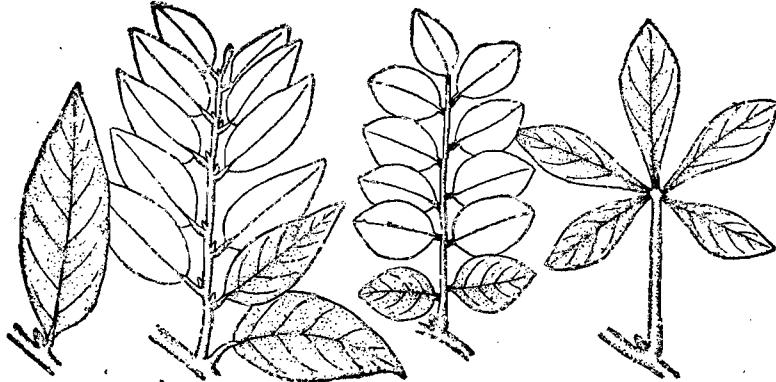

FIG. 101

FIG. 102

FIG. 104

FIG. 101. A simple leaf. FIG. 102. A branch. FIG. 103. A pinnately compound leaf with the leaflets articulated to the mid-rib. FIG. 104. A palmately compound leaf with the leaflets articulated to the petiole. Note the position of the bud in each case.

leaflets of a compound leaf have no axillary buds ; whereas the leaves (simple) borne on a branch have a bud in their axil ; and (4) a branch is always provided with nodes and internodes ; while the rachis of a compound leaf is free of them.

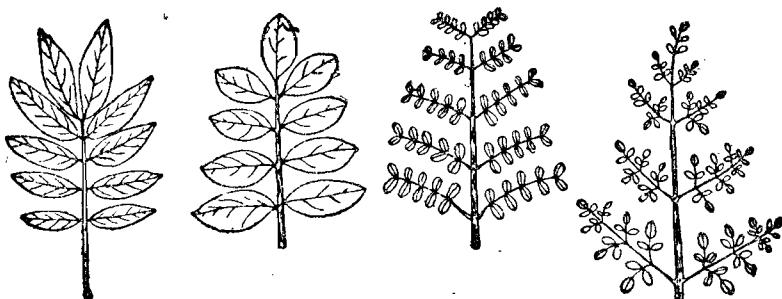

FIG. 105

FIG. 107

FIG. 108

Pinnate Leaves. FIG. 105. Unipinnate (paripinnate). FIG. 106. Unipinnate (imparipinnate). FIG. 107. Bipinnate. FIG. 108 Tripinnate.

1. Pinnately Compound Leaf. A pinnately compound leaf is defined as the one in which the mid-rib, known as the **rachis**, bears *laterally* a number of leaflets, arranged alternately or in

an opposite manner, as in tamarind, gram, gold mohur, rain tree, sensitive plant, gum tree (*Acacia*), *Cassia* (B. KALKASUNDE ; H. KASONDI), etc. It may be of the following types:

(1) **Unipinnate** (figs. 105-6). When the mid-rib of the pinnately compound leaf directly bears the leaflets, it is said to be unipinnate. In it the leaflets may be *even* in number (**paripinnate** ; fig. 105), as in *Saraca* (B. ASOK ; H. SEETA-ASOK), *Cassia*, etc., or *odd* in number (**imparipinnate** ; fig. 106), as in rose, margosa (B. & H. NIM), etc.

(2) **Bipinnate** (fig. 107). When the compound leaf is twice pinnate, i.e. the mid-rib produces secondary axes which bear

the leaflets, it is said to be bipinnate, as in dwarf gold mohur, gum tree, sensitive plant, etc.

(3) **Tripinnate** (fig. 108). When the leaf is thrice pinnate, i.e. the secondary axes produce the tertiary axes which bear the leaflets, the leaf is said to be tripinnate, as in drumstick (*Moringa* ; B. SAJINA ; H. SAINJNA), and *Oroxylon* (B. SONA ; H. ARLU).

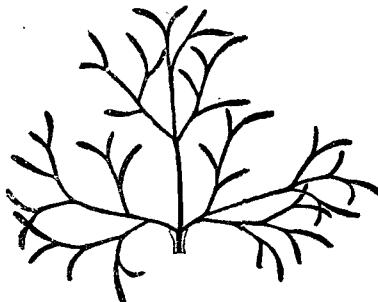

FIG. 109. Decomound leaf of coriander.

Palmate Leaves. FIG. 110. Multifoliate leaf of *Gynandropsis*. FIG. 111. The same of silk cotton tree (*Bombax*). FIG. 112. Unifoliate compound leaf of pummelo; P, winged petiole.

(4) **Decompound** (fig. 109). When the leaf is more than thrice pinnate, it is said to be decompound, as in anise, carrot, coriander, *Cosmos*, etc.

2. **Palmately Compound Leaf** (figs. 110-2). A palmately compound leaf is defined as the one in which the petiole bears *terminally*, articulated to it, a number of leaflets which seem to be radiating from a common point like fingers from the palm, as in silk cotton tree, lupin, *Gynandropsis* (B. SWET-HURHURE; H. HURHUR), etc. Leaflets are commonly 5 or more (multifoliate or digitate) as in silk cotton tree, sometimes 3 (trifoliate) as in wood-apple and wood-sorrel, rarely 1 (unifoliate) as in pummelo or shaddock, lemon and orange, or 2 (bifoliate), or 4 (quadrifoliate) as in *Marsilea* (B. SHUSHNI-SAK).

MODIFICATIONS OF LEAVES

Leaves of many plants which have to perform specialized functions become modified or metamorphosed into distinct forms. These are as follows.

1. **Leaf-tendrils** (fig. 113-6). In some plants leaves are modified into slender, wiry, often closely coiled structures known as tendrils. Tendrils are always climbing organs and are sen-

FIG. 113

FIG. 114

FIG. 115

Leaf-tendrils. FIG. 113. Pea leaf with upper leaflets modified into tendrils. FIG. 114. Wild pea (*Lathyrus*) with the entire leaves modified into tendrils. *T*, tendrils; *S*, stipules. FIG. 115. Glory lily (*Gloriosa*) with the leaf-apex modified into a tendril.

sitive to contact with a foreign body. Therefore, whenever they come in contact with a neighbouring object they coil round it and help the plant to climb. The leaf may be partially or wholly modified. Thus in pea (fig. 113) only the upper leaflets are modified into tendrils, while in wild pea (*Lathyrus*; fig. 114) the whole leaf is modified into a tendril. In traveller's joy (*Naravelia*; fig. 116) the terminal leaflet alone is modified into a tendril, while in glory lily (*Gloriosa*; B. ULAT-CHANDAL; H. KALIARI—fig. 115) the leaf-apex only is so modified. In sarsaparilla (*Smilax*; B. KUMARIKA; H. CHOB-CHINI) the stipules are modified into tendrils (see fig. 88).

FIG. 116. Leaf of *Naravelia* with the terminal leaflet modified into a tendril (t).

2. Leaf-spines (figs. 117-8). Leaves of certain plants become wholly or partially modified for defensive purpose into sharp, pointed structures known as **spines**. Thus in prickly pear (B. PHANI-MANSHA; H. NAGPHANI—see fig. 74A) the minute leaves of the axillary bud are modified into spines. The leaf-apex in

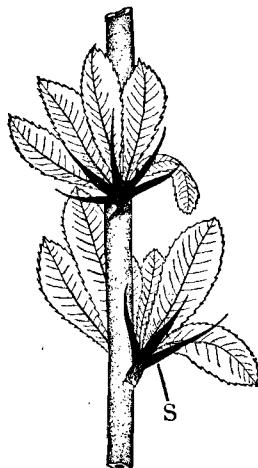

FIG. 117

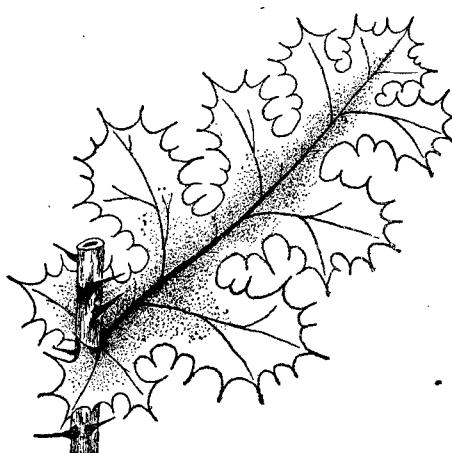

FIG. 118

Leaf-spines. FIG. 117. Barberry. Primary leaves modified into spines (S).
FIG. 118. Leaf of prickly poppy (*Argemone*) showing spines.

date-palm, dagger plant (see fig. 136), etc., is so modified, while in plants like prickly poppy (B. SHEAL-KANTA; H. PILA-DHUTURA

—fig. 118), American aloe, etc., spines develop on the margin as well as at the apex. In barberry (fig. 117) the leaf itself becomes modified into a spine; while the leaves of the axillary bud are normal.

3. **Scale-leaves.** Typically these are thin, dry, stalkless, membranous structures, usually brownish in colour or sometimes colourless. Their function is to protect the axillary bud that they bear in their axil. Sometimes scale-leaves are thick and fleshy, as in onion; then their function is to store up water and food. Scale-leaves are common in parasites, saprophytes, underground stems, etc. They are also found in *Casuarina* (B. & H. JHAU), *Asparagus*, etc.

4. **Phyllode** (fig. 119). In Australian *Acacia* the petiole or any part of the rachis becomes flattened or winged taking the

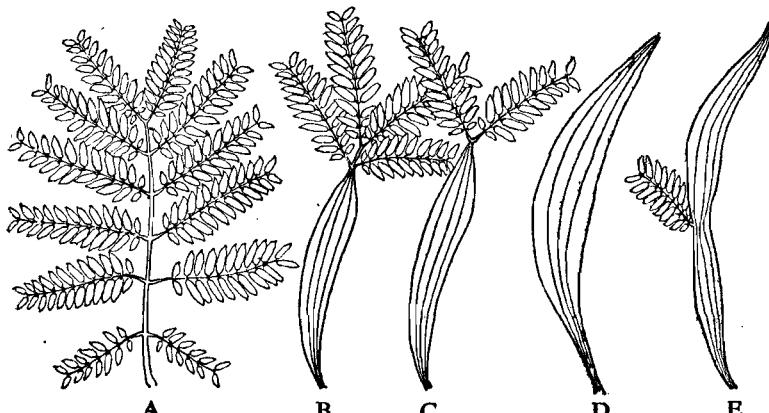

FIG. 119. Development of phyllode in Australian *Acacia*. A, pinnately compound leaf; B-C, petiole developing into phyllode; D, phyllode; and E, petiole and rachis developing into phyllode.

shape of the leaf and turning green in colour. This flattened or winged petiole or rachis is known as the **phyllode**. The normal leaf which is pinnately compound in nature always develops in the seedling stage, but it soon falls off. The phyllode then has all the functions of the leaf. In some species young or even adult plants are seen to bear the normal compound leaf together with the phyllode. There are about 300 species of Australian *Acacia*, all showing the phyllode.

5. **Pitcher** (figs. 120-1). In the pitcher plant (*Nepenthes*) the leaf becomes modified into a **pitcher**. The pitcher may be as big

as 20-23 cm. in height, sometimes a little more. It has a strong

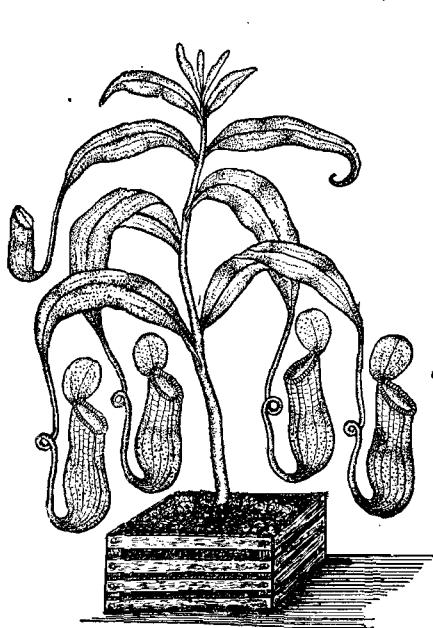

FIG. 120

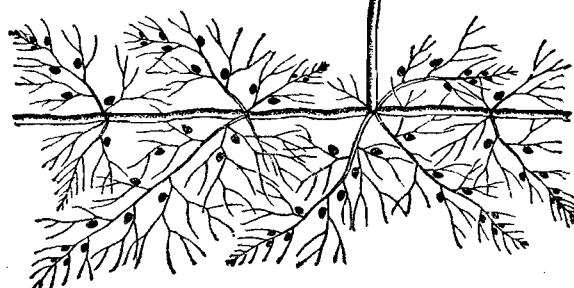

FIG. 120. Pitcher plant (*Nepenthes*). FIG. 121. A pitcher.

stalk which often coils like a tendril holding the pitcher verti-

with many
small bladders;
top, a bladder in
section (magnified).

cal, and the basal portion is flattened like a leaf. The pitcher is

provided with a lid which covers its mouth when the pitcher is young. The function of the pitcher is to capture and digest insects.

6. **Bladder** (fig. 122). Bladderwort (*Utricularia*) is a very common carnivorous plant found floating in tanks. The leaf of this plant is very much segmented. Some of these segments are modified to form bladder-like structures, with a trap-door entrance which allows aquatic animalcules to pass in, but never to come out.

PHYLLOTAXY

The term phyllotaxy (*phylla*, leaves ; *taxis*, arrangement) means the various modes in which the leaves are arranged on the stem or the branch. The object of this arrangement is to avoid shading one another so that the leaves may get the maximum amount of sunlight to perform their normal functions, particularly manufacture of food. Three principal types of phyllotaxy are noticed in plants.

(1) **Alternate** or **Spiral** (fig. 123), when a single leaf arises at each node, as in tobacco, China rose, mustard, sunflower, etc.

(2) **Opposite** (fig. 124), when two leaves arise at each node standing opposite each other. In opposite phyllotaxy one pair of leaves is most commonly seen to stand at a right angle to the next upper or lower pair. Such an arrangement of leaves

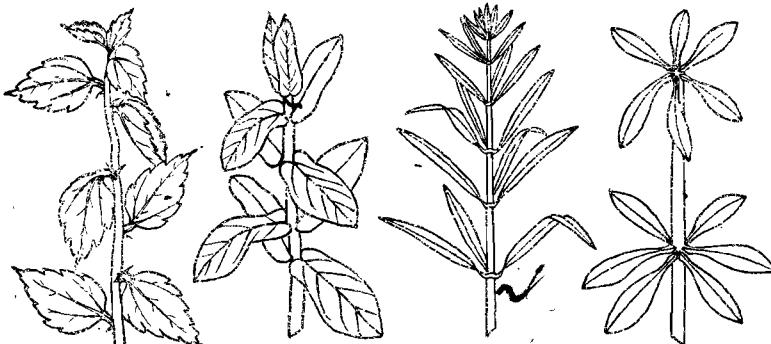

FIG. 123

FIG. 124

FIG. 125

FIG. 126

Types of Phyllotaxy. FIG. 123. Alternate phyllotaxy of China rose. FIG. 124. Opposite phyllotaxy of madar (*Calotropis*). FIG. 125. Whorled phyllotaxy of oleander (*Nerium*). FIG. 126. Ditto of devil tree (*Alstonia*).

is said to be decussate, as in sacred basil (*Ocimum*; B. & H. TULSI), madar (*Calotropis*; B. AKANDA; H. AK), guava, etc.

Sometimes, however, a pair of leaves is seen to stand directly over the lower pair in the same plane. Such an arrangement of leaves is said to be **superposed**, as in Rangoon creeper (*B. SANDHYA-MALATI*; *H. LAL-MALTI*).

(3) **Whorled** (figs. 125-6), when there are more than two leaves at each node and these are arranged in a circle or whorl, as in devil tree (*Alstonia*; *B. CHHATIM*; *H. CHATIUM*), oleander (*Nerium*; *B. KARAVI*; *H. & P. KANER*), etc.

Alternate Phyllotaxy. The leaves in this case are seen to be spirally arranged round the stem. Now, if an imaginary spiral line starting from any leaf be passed round the stem through the bases of the successive leaves, it is seen that the spiral line finally reaches a leaf which stands vertically over the starting leaf. The imaginary spiral line that may pass round through the bases of successive leaves is known as the **genetic spiral**, and the vertical line, i.e. the vertical row of leaves, known as the **orthostichy** (*orthos*, straight; *stichos*, line).

(1) **Phyllotaxy $\frac{1}{2}$** or **distichous** (fig. 128). In grasses, traveller's tree (fig. 127), ginger, *Vanda* (see fig. 57), etc., the *third* leaf always stands over the *first* (starting anywhere).

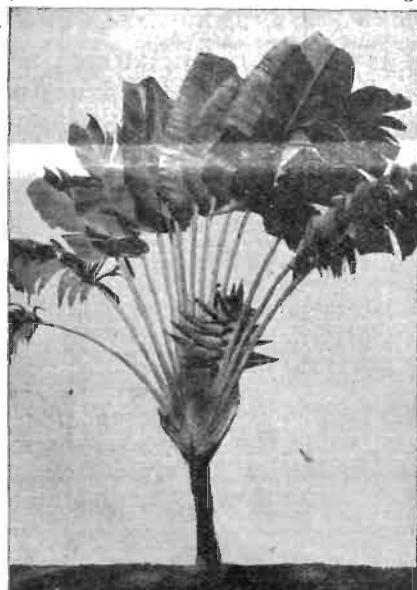

FIG. 127. Traveller's tree (*Ravenala*) showing distichous phyllotaxy.

Thus there are only *two* orthostichies, i.e. two rows of leaves, and, therefore, the phyllotaxy is distichous. From the starting leaf to the third leaf the genetic spiral makes only *one* turn. Leaves are thus placed at half the distance of a circle, and the phyllotaxy is expressed by the fraction $\frac{1}{2}$, the numerator indicating 1 turn of the genetic spiral and the denominator the number of intervening leaves, i.e. 2 (leaving out the third leaf which stands over the first).

The genetic spiral makes one complete turn in this case, subtending an angle of 360° in the centre of the circle, and it involves two leaves; so the **angular divergence**, that is, the angular distance between any two consecutive leaves, is $\frac{1}{2}$ of 360° , i.e. 180° .

(2) **Phyllotaxy $\frac{1}{3}$** or **tristichous** (fig. 129). In sedges (B. & H. MUTHA) the fourth leaf stands vertically over the first one, and the genetic spiral makes *one* turn to reach that leaf, and it in-

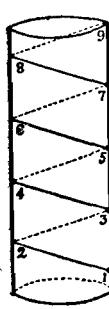

FIG. 128

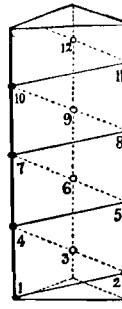

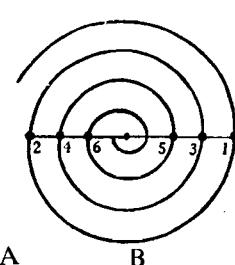

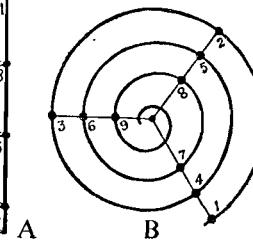

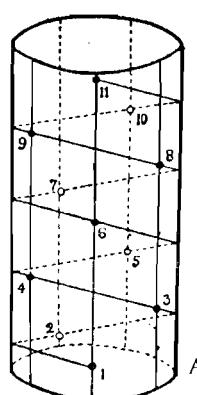

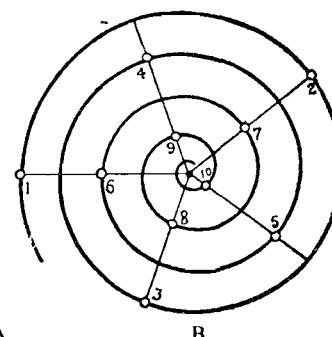

FIG. 129

volves three leaves. Thus there are *three* orthostichies, i.e. three rows of leaves. Leaves can be seen placed at one-third the distance of a circle. Phyllotaxy is, therefore, tristichous or $\frac{1}{3}$. The angular divergence is $\frac{1}{3}$ of 360° , i.e. 120° .

(3) **Phyllotaxy $\frac{2}{5}$** or **pentastichous** (fig. 130). In China rose the sixth leaf stands over the first, and the genetic spiral completes

FIG. 130. A, phyllotaxy $\frac{2}{5}$; B, angular divergence 144° .

two circles to come to that particular leaf. Thus there are five orthostichies, i.e. five rows of leaves, and two turns of the genetic spiral involving five leaves. The latter can be seen placed at two-fifths the distance of a circle. Phyllotaxy is, therefore, pentastichous or $\frac{2}{5}$. This is the commonest type of alternate phyllotaxy. The angular divergence in this case is $\frac{2}{5}$ of 360° , i.e. 144° .

(The same fraction can also be arrived at by adding separately the numerators and the denominators of the two previous cases, e.g. $\frac{1+1}{2+3} = \frac{2}{5}$. The next case will, therefore, be $\frac{1+2}{3+5} = \frac{3}{8}$, and so on. Fractions higher than $\frac{2}{5}$ are not commonly met with.)

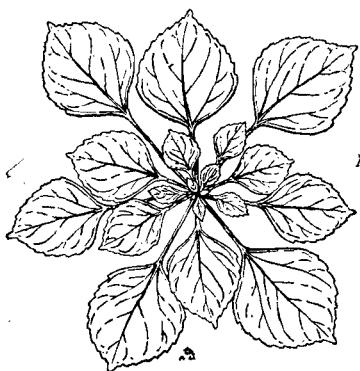

FIG. 131. Leaf mosaic of *Acalypha*.

such a way that they may secure the maximum amount of sunlight with the minimum amount of overlapping.

Functions of the Leaf. Normal functions of the green foliage leaf are threefold: (1) manufacture of food material, (2) interchange of gases between the atmosphere and the plant body, and (3) evaporation of excess of water through the leaf. Besides, the fleshy leaf is used to store up water and food. In a few cases the leaf produces buds on it for vegetative propagation of the plant. The leaf also gives necessary protection to the bud in its axil. A modified leaf has a specialized function (see pp. 61-5).

(1) **Manufacture of Food.** The primary function of the leaf is to manufacture food, particularly sugar and starch, during the daytime only, i.e. in the presence of sunlight which is the original source of energy to the plant. The leaf manufactures food with the help of chloroplasts contained in it, out of water and carbon dioxide obtained from the soil and the air respec-

Leaf Mosaic. In the floors, walls and ceilings of many temples and decorated buildings we find setting of stones and glass pieces of variegated colours and sizes into particular designs. Each such design is known as a mosaic. Similarly, in plants we find the setting or distribution of leaves in some definite designs. Each such design of leaf-distribution is known as **leaf mosaic**. Leaves are in special need of sunlight for manufacture of food material, and this being so, they tend to fit in with one another and adjust themselves in

tively. The upper side of the leaf is deeper green in colour with more abundant chloroplasts, and also the sunlight falls directly on the upper surface and, therefore, food manufacture normally takes place in this region.

(2) **Interchange of Gases.** Through the lower surface of the leaf a regular exchange of gases takes place between the atmosphere and the plant body through numerous very minute openings, called **stomata** (see fig. 297) which remain open during daylight only. The gases concerned are oxygen and carbon dioxide. This exchange of gases is mainly for the purpose of *respiration* by all the living cells which absorb oxygen and give out carbon dioxide, and also for the purpose of *food manufacture* by green cells only which absorb carbon dioxide and give out oxygen.

(3) **Evaporation of Water.** The excess water absorbed by the root-hairs evaporates during the daytime through the surfaces of the leaf, mainly through the stomata. At night the excess water sometimes escapes in liquid form through the apices of veins, particularly in herbaceous plants.

(4) **Storage of Food.** Fleshy leaves of Indian aloe (*B. CHRITAKUMARI*; *H. CHIKAVAR*), *Portulaca* (*B. NUNIA-SAK*; *H. KULFA-SAG*) and fleshy scales of onion store up water and food for their future use. Fleshy and succulent leaves of desert plants always store a quantity of water, mucilage and food.

(5) **Vegetative Propagation.** Leaves of sprout leaf plant (*Bryophyllum*; see fig. 60), elephant-ear plant (*Begonia*; see fig. 61) produce buds on them for vegetative propagation of such plants. Walking ferns reproduce vegetatively by their leaf-tips. Leaves bow down, and their tips touching the ground strike roots and form a bud which grows into a new plant (see fig. 358).

Heterophyllly. Many plants bear different kinds of leaves on the same individual plant. This condition is known as **heterophyllly** (*heteros*, different; *phylla*, leaves). Heterophyllly is met with in many aquatic plants, particularly in those growing in shallow running water. Here the floating leaves and the submerged leaves are of different kinds; the former are generally broad, more or less fully expanded, and undivided or merely lobed, while the latter are narrow, ribbon-shaped, linear or much dissected. Heterophyllly in water plants is regarded as an adaptation to two different conditions of the environment.

Common examples are *Cardenthera triflora* (fig. 132), water crowfoot (*Ranunculus aquatilis*), arrowhead (*Sagittaria*; fig. 135),

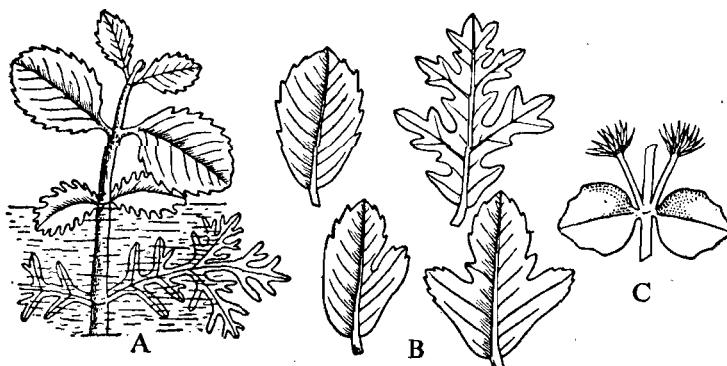

FIG. 132

Heterophyly. FIG. 132. *Cardenthera triflora*. FIG. 133. *Artocarpus chaplasha*. FIG. 134. *Hemiphragma heterophyllum*.

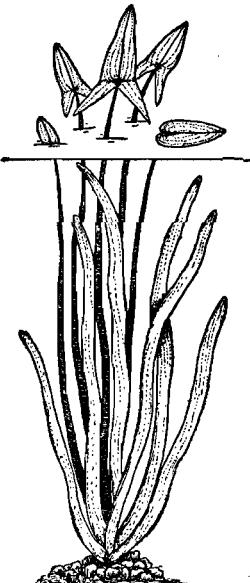

Limnophila heterophylla, etc. Some land plants also exhibit this phenomenon without any apparent reason. Common ex-

amples are *Artocarpus chaplasha* (fig. 133), *Hemiphragma heterophyllum* (fig. 134), *Ficus heterophylla*, etc. In *Hemiphragma* the leaves are of two kinds—broad and needle-shaped.

Homology and Analogy. Homology is the morphological study of modified organs from the standpoint of their origin, and analogy is the study of organs from the standpoint of their identical structure and function; or, in other words, organs which resemble one another in their origin, and are, therefore, morphologically the same, whatever be their structure and function, are said to be *homologous* with one another, and organs which resemble one another in their structure and are adapted to the performance of identical functions, although their origin is different, are said to be *analogous* with one another. Thus all tendrils, whatever be their position, are analogous with one another, being structurally the same and having the same

FIG. 135. Arrowhead showing heterophyly.

function; but tendrils of passion-flower (see fig. 70) are homologous with axillary buds, i.e. modifications of the latter, and tendrils of pea (see fig.

113) are homologous with leaflets. Similarly tendrils of passion-flower and thorns of *Duranta* (see fig. 73A) are homologous structures, both having the same origin in the axils of leaves as modifications of axillary buds. Likewise the rhizome, the tuber, the fusiform root, the napiform root, etc., are analogous structures, being adapted to the performance of identical function, i.e., storage of food; but it must be noted that the former two (rhizome and tuber) are homologous with the stem, being modifications of it, while the latter two (fusiform root and napiform root) are homologous with the root, being modifications of it.

CHAPTER 7 *Defensive Mechanisms in Plants*

The animal kingdom as a whole is directly or indirectly parasitic upon the plant kingdom, and this being so, plants must either fall a victim to various classes of animals, particularly the herbivorous ones, which live exclusively on a vegetable diet, or they must be provided with special organs or arms of defence, or have other special devices to repulse or avoid the attack of their enemies. Being fixed to the ground they cannot, of course, manoeuvre, when attacked by animals.

1. Armature. Various parts of the plant body may take the form of arms or defensive weapons for self-defence against the attack of herbivorous animals. These are as follows.

(1) **Thorns** (see p. 45) are modifications of branches, and originate from deeply-seated tissues of the plant body. They are straight, hard and pointed, and can pierce the body of thick-skinned animals. Plants like wood-apple, *Vangueria* (B. MOYENA), lemon, pomegranate, *Duranta*, *Carissa* (B. KARANJA ; H. KARONDA) and many others are well provided with thorns for self-defence.

(2) **Spines** (see p. 62) are modifications of leaves or parts of leaves, and serve the purpose of defence. They are seen in pineapple, date-palm, prickly poppy (see fig. 118), American aloe, dagger plant, etc. In dagger plant (fig. 136) each leaf ends in a very sharp and pointed spine, and is directed outwards. It acts like a dagger or pointed spike when any grazing animal approaches it.

(3) **Prickles** (see also pp. 3-4) are also hard and pointed like the thorns, but are usually curved and have a superficial origin ; they are further irregularly distributed on the stem, branch or leaf. Prickles are commonly found in rose (see fig. 6), cane (see fig. 5), coral tree, silk cotton tree, *Prosopis* (B. &

H. SHOMI), etc. Globe thistle and prickly poppy (see fig. 118) are armed with both prickles and spines for self-defence.

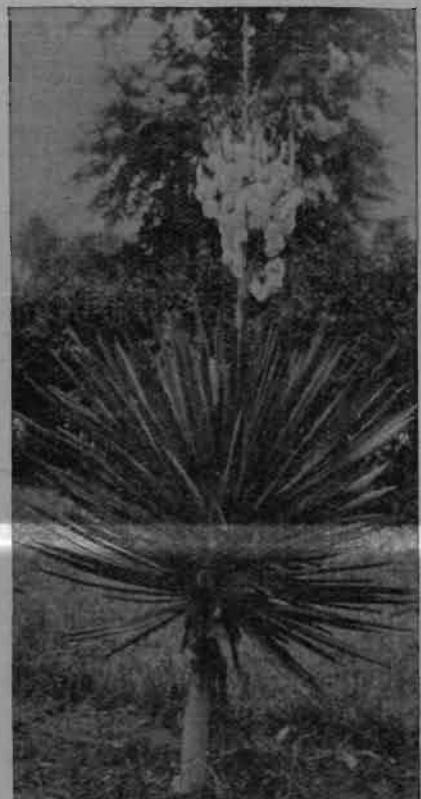

FIG. 136. Dagger plant or Adam's needle (*Yucca*).

the swollen base of the hair, causing a sharp burning pain, often attended with inflammation. There are various kinds of nettles, e.g. *Fleurya* (B. LAL-BICHUTI)—an annual weed; *Tragia* (B. BICHUTI ; H. BARHANTA)—a twiner, fever or devil nettle (*Laportea*)—a shrub, cowage (*Mucuna*; B. ALKUSHI ; H. KAWANCH)—a large twiner, etc. In cowage the stinging hairs develop on the fruit.

(6) **Hairs.** A dense coating of hairs or presence of stiff hairs on the body of the plant is always repulsive to animals as these hairs stick on to their throat and cause a choking sensation, e.g. cud-weed (*Gnaphalium*). Many plants bear **glandular hairs** which secrete a sticky substance. Any animal feeding upon

(4) **Bristles** are short, stiff and needle-like hairs, usually growing in clusters, and not infrequently barbed. Their walls are often thickened with a deposit of silica or calcium carbonate. Bristles are commly met with in prickly pear (B. PHANIMANSHA ; H. NAGPHANI—see fig. 73A) and in many other cacti.

(5) **Stinging Hairs.** Nettles (B. BICHUTI ; H. BARHANTA) develop stinging hairs on their leaves or fruits or all over their body. Each hair (fig. 137) has a sharp siliceous apex which readily breaks off even when touched lightly. The sharp point penetrates into the body, inflicts a wound into which the acid poison of the hair is forced by the sudden pressure exerted on

such a plant finds it difficult to brush them off from its mouth. Plants bearing glandular hairs are thus never attacked by grazing animals, e.g. tobacco, *Boerhaavia* (B. PUNARNAVA ; H. THIKRI or SANT), *Jatropha* (B. & H. BHARENDI), *Plumbago* (B. CHITA ; H. CHITRAK), etc.

2. Other Devices of Defence. Many plants secrete poisonous and irritating substances ; such plants are carefully avoided by animals which possess the power of distinguishing between poisonous and non-poisonous ones.

(1) **Latex** is the milky juice secreted by certain plants. It always contains some waste products, and often irritating and poisonous substances so that it causes inflammation and even blisters when it comes in contact with the skin. Plants like madar, *Euphorbia* (B. & H. SIJ and MANASHA-SIJ), celandine, periwinkle, banyan, fig, poppy, papaw, etc., contain latex.

(2) **Alkaloids** are in many cases extremely poisonous, and a very minute quantity is sufficient to kill a strong animal. There are various kinds of them found in plants, e.g. strychnine in nux-vomica, morphine in opium poppy, nicotine in tobacco, daturine in *Datura*, quinine in *Cinchona*, etc.

(3) **Irritating Substance.** Plants like many aroids, e.g. taro (*Colocasia* ; B. KACHU ; H. KACHALU), *Amorphophallus* (B. OL ; H. KANDA), etc., possess needle-like or otherwise sharp and pointed crystals of calcium oxalate, i.e. raphides (see figs. 270-2). These crystals, when such plants are fed upon, prick the tongue and the throat and cause irritation. Therefore, such plants are never attacked by grazing animals.

(4) **Bitter Taste and Repulsive Smell.** These are also effective mechanisms to ward off animals. *Paederia foetida* (B. GANDHAL ; H. GANDHALI) emits a bad smell so that no animal likes to go near it. Plants like sacred basil, mint, *Blumea lacera* (B. KUKURSONGA ; H. KOKRONDA), *Gynandropsis*, etc., also emit a strong disagreeable odour. The fetid smell of the inflorescence of *Amorphophallus* (see fig. 201) is very offensive and nauseating. Margosa, bitter gourd, *Andrographis* (B. KALMEGH ; H. MAHATITA), etc., have a bitter taste and, therefore, animals avoid them.

FIG. 137
A stinging hair.

(5) **Waste Products.** Many plants contain various waste products such as tannin, resin, essential oils, raphides, silica, etc., which keep them free from the attack of animals.

(6) **Mimicry.** Certain plants also protect themselves against grazing animals by imitating the general appearance, colour,

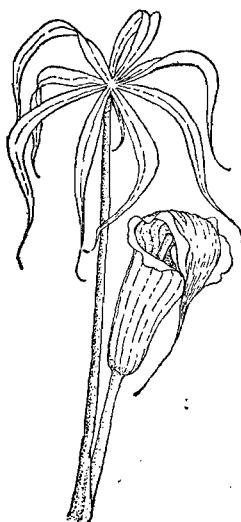

FIG. 138. Snake or cobra plant (*Arisaema*).

any particular feature of another plant or animal, is called **mimicry** (*mimikos*, imitative).

Plants have also to protect themselves against the attack of many parasitic fungi and gnawing insects, and also against the scorching rays of the sun ; this they do by developing cork and bark.

CHAPTER 8 *The Inflorescence*

The branch system of the floral region bearing a group of flowers is called **inflorescence**. Thus depending on the mode of branching different kinds of inflorescence have come into existence, and these may primarily be classified into two distinct groups, viz. **racemose** or **indefinite** and **cymose** or **definite**.

i. Racemose Inflorescences. Here the main axis of inflorescence does not end in a flower, but it continues to grow and give off flowers laterally. The lower or outer flowers are always older

shape or particular feature of another plant or animal, which has developed a special weapon of defence ; for instance, there are certain aroids (e.g. varieties of *Caladium*) which resemble multi-coloured and variously spotted snakes. Leaves are also variously spotted and striped in many species of bowstring hemp (*Sansevieria*; B. MURGA; H. MARUL) and other allied plants. Herbivorous animals, possibly mistaking them for snakes or some other threatening creatures carefully avoid them. In snake plant (*Arisaema*; fig. 138), common in Shillong during the rains, the spathe is greenish-purple in colour and it expands over the spadix like the hood of the cobra. This act of imitating the appearance, colour or

and open earlier than the upper or inner ones. Some of the common types are as follows.

I. WITH THE MAIN AXIS ELONGATED

(1) **Raceme** (fig. 139). The main axis in this case is elongated and it bears laterally a number of flowers which are all stalked,

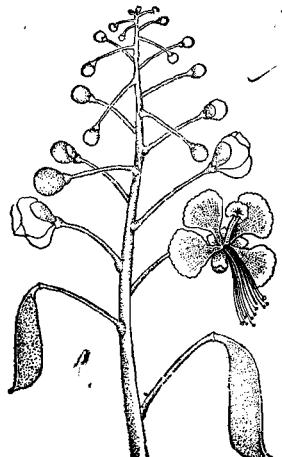

FIG. 139

FIG. 140

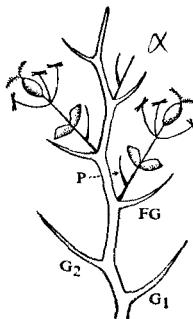

FIG. 141

FIG. 142

Racemose Inflorescences. FIG. 139. Raceme of dwarf gold mohur. FIG. 140. Spike (diagrammatic). FIG. 141. Spikelet of a grass (diagrammatic); G_1 , first empty glume; G_2 , second empty glume; FG , flowering glume (lemma); and P , palea. FIG. 142. Female catkin of mulberry.

the lower or older flowers having longer stalks than the upper or younger ones, as in radish, mustard, dwarf gold mohur, fever nut (*B. NATA*; *H. KATKARANJ*), etc.

When the main axis of the raceme is branched and the lateral branches bear the flowers, the inflorescence is said to be a compound raceme or **panicle** (fig. 143), as in gold mohur.

The main axis of the inflorescence together with the lateral axes, if present, is known as the **peduncle**. The stalk of the individual flower of the inflorescence is called the **pedicel**. In some solitary flowers such as China rose, gold mohur (see fig. 152), etc., the peduncle and the pedicel may be clearly marked out due to the presence

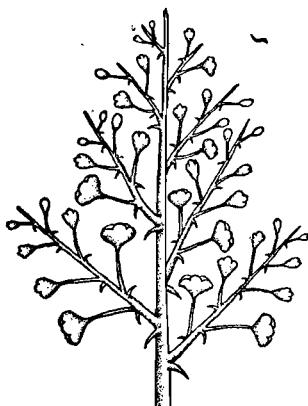

FIG. 143. A panicle.

of an articulation on the floral axis. When the peduncle of an inflorescence is short and dilated forming a sort of convex platform, as in sunflower (see fig. 148), or becoming hollow and pear-shaped, as in fig (*Ficus*), it is often called **receptacle** (see fig. 153).

(2) **Spike** (fig. 140). Here also the main axis is elongated and the lower flowers are older, opening earlier than the upper ones, as in raceme, but the flowers are sessile, that is, without any stalk. Examples are seen in tuberose, *Adhatoda* (B. BASAK ; H. ADALSA), amaranth (B. NATE-SAK ; H. CHULAI), chaff-flower (*Achyranthes* ; B. APANG ; H. LATJIRA), etc.

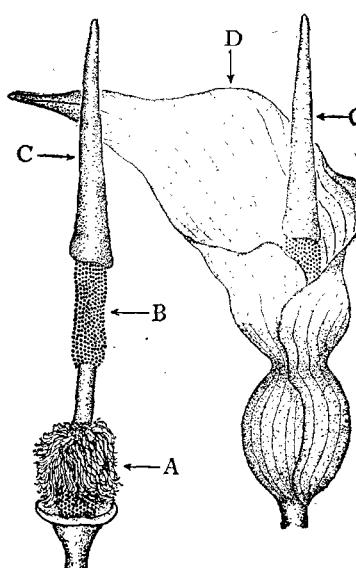

FIG. 144. Spadix of an aroid (*Typhonium*) ; A, female flowers; B, male flowers; C, appendix; D, spathe.

(3) **Spikelet** (fig. 141). This is a very small spike with one or a few small flowers (florets). In it there are two small *empty glumes* at the base, and just above them a *flowering glume* called *lemma* with a flower in its axil, and opposite to the lemma there is a small 2-nerved bracteole, called the *palea*. The flower remains enclosed by the lemma and the palea. Succeeding flowers likewise occur within the lemma and the palea. Spikelet is characteristic of the grass family, e.g. grasses, paddy, wheat, sugarcane, bamboo, etc.

(4) **Catkin** (fig. 142). This is a spike with a long and pendulous axis which bears unisexual flowers only, e.g. mulberry, *Acalypha densiflora*, birch and oak.

(5) **Spadix** (fig. 144). This is also a spike with a fleshy axis which is enclosed by one or more large, often brightly coloured bracts, called spathes, as in aroids, banana and palms. The spadix is found in monocotyledons only.

II. WITH THE MAIN AXIS SHORTENED

(6) **Corymb** (fig. 145). Here the main axis is comparatively short, and the lower flowers have much longer stalks or pedicels than the upper ones so that all the flowers are brought more or less to the same level, as in candytuft and wallflower.

(7) **Umbel** (figs. 146-7). Here the primary axis is shortened, and it bears at its tip a group of flowers which have pedicels of more or less equal lengths so that the flowers are seen to

spread out from a common point. In the umbel there is always a whorl of bracts forming an involucre, and each flower develops from the axil of a bract. Commonly the umbel is branched

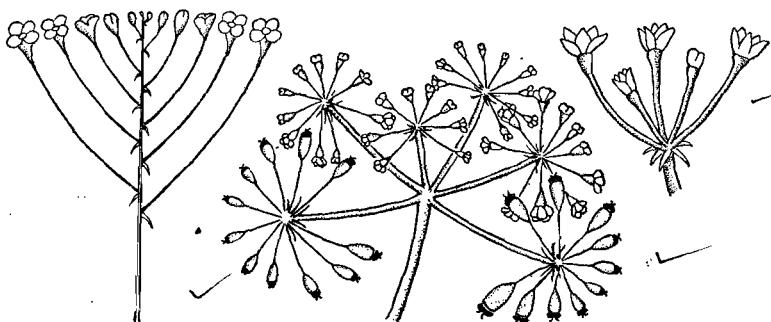

FIG. 145
FIG. 145. Corymb (diagrammatic).

FIG. 146

FIG. 146. Umbels. FIG. 146. A compound umbel.
FIG. 147. A simple umbel.

(**compound umbel**) and the branches bear the flowers, as in anise or fennel, coriander, cumin, carrot, etc. Sometimes, however, it is simple or unbranched (**simple umbel**), the main axis directly bearing the flowers, as in Indian pennywort and wild coriander. Umbel is characteristic of coriander family.

III. WITH THE MAIN AXIS FLATTENED

(8) **Head or Capitulum** (fig. 148). Here the main axis or receptacle is suppressed, becoming almost flat, and it bears a mass of small sessile flowers (florets) on its surface, with one or more whorls of bracts at the base forming an *involucre* (see p. 84). In the head the outer flowers are older and open earlier than the inner ones. The florets are commonly of two kinds—**ray florets** (marginal strap-shaped ones) and **disc florets** (central tubular ones). The head may also consist of only one kind of florets. A head or capitulum is characteristic of sunflower family (e.g. sunflower, marigold, safflower, *Zinnia*, *Cosmos*, etc.). It is also found in gum tree (*Acacia*), sensitive plant, *Anthoclephalus* (B & H. KADAM), etc.

The advantage of this kind of inflorescence is that the head as a whole becomes more showy and attractive, and one or a few insects can pollinate most of the flowers within a short time.

2. **Cymose Inflorescences.** Here the main axis ends in a flower and similarly the lateral axis also ends in a flower. Thus the growth of each axis is checked. In cymose inflorescences the

terminal flower is always older and opens earlier than the lateral ones.

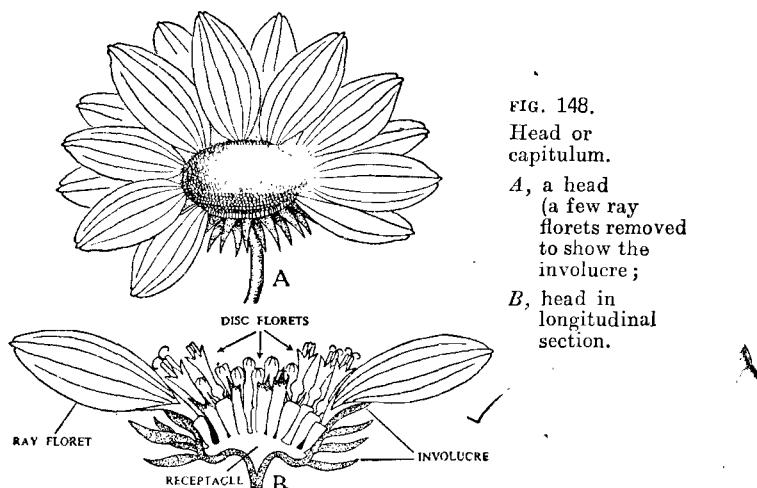

FIG. 148.
Head or
capitulum.

A, a head
(a few ray
florets removed
to show the
involucre;

B, head in
longitudinal
section.

In the cymose inflorescence when two lateral axes develop at a time and more or less equally, it is called a true cyme (fig. 149), as a jasmines, teak, pink, *Ixora* (B. RANGAN; H. GOTAGANDHAL), etc. In some plants, however, it is seen that only one lateral axis develops at a time, while the other one remains suppressed. Thus when the lateral axes develop successively on the same side, forming a sort of helix, as in

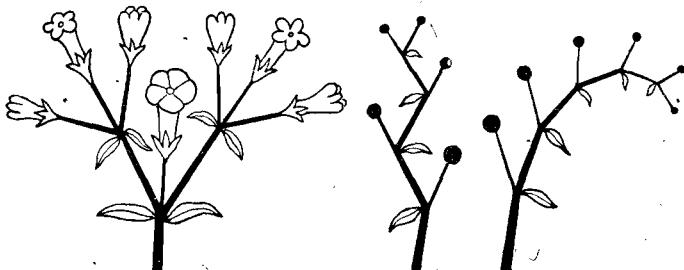

FIG. 149.
Cymose Inflorescences. FIG. 149. Biparous cyme. FIG. 150. Scorpioid
cyme. FIG. 151. Helicoid cyme.

Begonia, rush, day lily and some plants of potato family, the cymose inflorescence is called a **helicoid cyme** or one-sided cyme (fig. 151). On the other hand when the lateral axes develop on alternate sides, evidently forming a zigzag, as in cotton, sundew, heliotrope (B. HATISUR; H. HATTASURA) and *Freesia*, the cymose inflorescence is called a **scorpioid cyme** or alternate-sided cyme (fig. 150).

3. **Special Types.** The following two types may be noted.

(1) **Verticillaster** (fig. 152). This is a special form of cymose inflorescence. In it there is a cluster of sessile or almost sessile flowers in the axil of a leaf, forming a false whorl at the node. The first axis gives rise to two lateral branches and these branches and the succeeding ones bear only one branch each on alternate sides. This kind of inflorescence is found in several members of basil family, e.g. *Coleus*, mint (B. PUDINA; H. PODINA), *Leonurus* (B. DRONA; H. HALKUSHA), etc. In sacred basil (B. & H. TULSI) the verticillaster is a condensed cyme, succeeding branches remaining undeveloped.

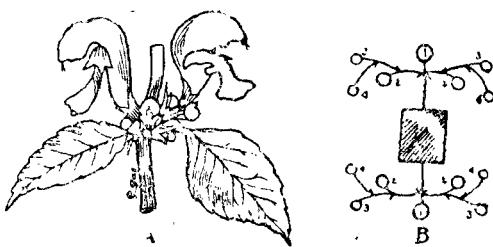

FIG. 152. Verticillaster of *Coleus*. A, verticillaster; B, diagram of verticillaster.

(2) **Hypanthodium** (fig. 153). When the fleshy receptacle forms a hollow cavity with an apical opening guarded by scales, and the flowers are borne on the inner wall of the cavity, the inflorescence is a hypanthodium,

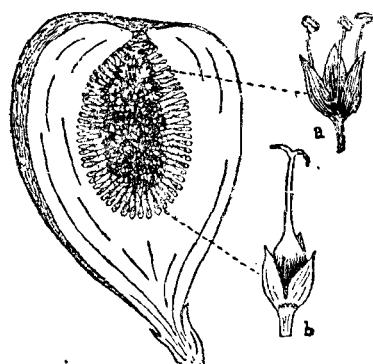

FIG. 153. Hypanthodium of fig (*Ficus*). a, male flower; b, female flower.

as in *Ficus* (e.g. banyan, fig, peepul, etc.) Here the female flowers develop at the base of the cavity and the male flowers higher up towards the apical pore.

Inflorescences

Racemose	Cymose	Special types
—raceme, e.g. radish	—true, e.g. jasmines	—verticillaster,
—spike, e.g. amaranth	—helicoid, e.g. <i>Begonia</i>	e.g. <i>Leonurus</i>

—corymb, e.g. candytuft		
—umbel, e.g. coriander		
—capitulum, e.g. sunflower		

CHAPTER 9 *The Flower*

The **flower** is a highly modified shoot meant essentially for the reproduction of the plant. Typically it is a collection of *four* different kinds of floral members arranged in *four* separate whorls or circles in a definite order. Of the four whorls

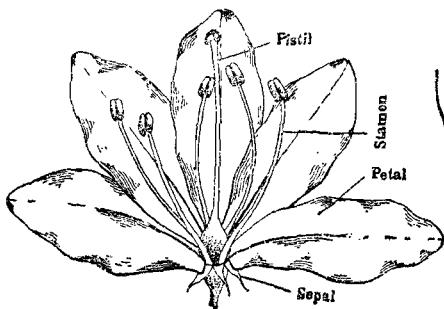

FIG. 154

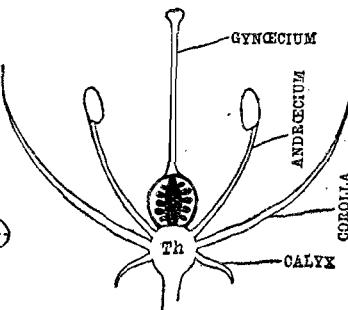

FIG. 155

FIG. 154, Parts of a flower. FIG. 155. A flower in longitudinal section showing the position of the whorls on the thalamus (*Th*).

the upper two are called *essential* or *reproductive* whorls, and the lower two *helping* or *accessory* whorls. The essential whorls take direct part in reproduction.

Parts of a Flower (figs. 154-6). The flower is commonly borne on a short or long axis. The axis itself is made up of two regions, viz. the **pedicel** which is the stalk of the flower, and the **thalamus** which is the swollen end of the axis with the floral leaves inserted on it. The pedicel may be short or long or even absent. A typical flower consists of *four* whorls arranged in a definite order, one just above the other. The whorls and their component parts are as follows.

(1) **Calyx** is the first or the lowermost whorl of the flower, and consists of a number of green leafy **sepals**.

(2) **Corolla** is the second whorl of the flower, and consists of a number of usually brightly coloured **petals**.

(3) **Androecium** (*andros*, male) is the third or the male whorl; its component parts are called **stamens**. Each stamen is made of three parts—**filament**, **anther** and **connective**. The anther bears four chambers or **pollen-sacs**, each filled with a granular mass of small (male) spores, called **pollen grains**.

(4) **Gynoecium** (*gyne*, female) or **pistil** is the fourth or the female whorl, and its component parts are called **carpels**. The gynoecium is made of three parts—**ovary**, **style** and **stigma**.

The ovary encloses some minute egg-like bodies known as the **ovules**. Each ovule encloses a large oval cell known as the **embryo-sac** (fig. 193).

Some Descriptive Terms. The flower is said to be **complete** when all the four whorls are present, and **incomplete** when any of them is absent. When both stamens and carpels are present the flower is said to be **bisexual** or **hermaphrodite**, and when any of them is absent the flower is said to be **unisexual**. The unisexual flower may, therefore, be **stamine** or **male** when only stamens are present, or, **pistillate** or **female** when only carpels are present. When both stamens and carpels are absent from a flower it is said to be **neuter**. When the calyx and corolla do not differ much in shape and colour, they together are said to form the **perianth** of the flower, as in lilies, tuberose, onion, garlic, *Asparagus*, etc.

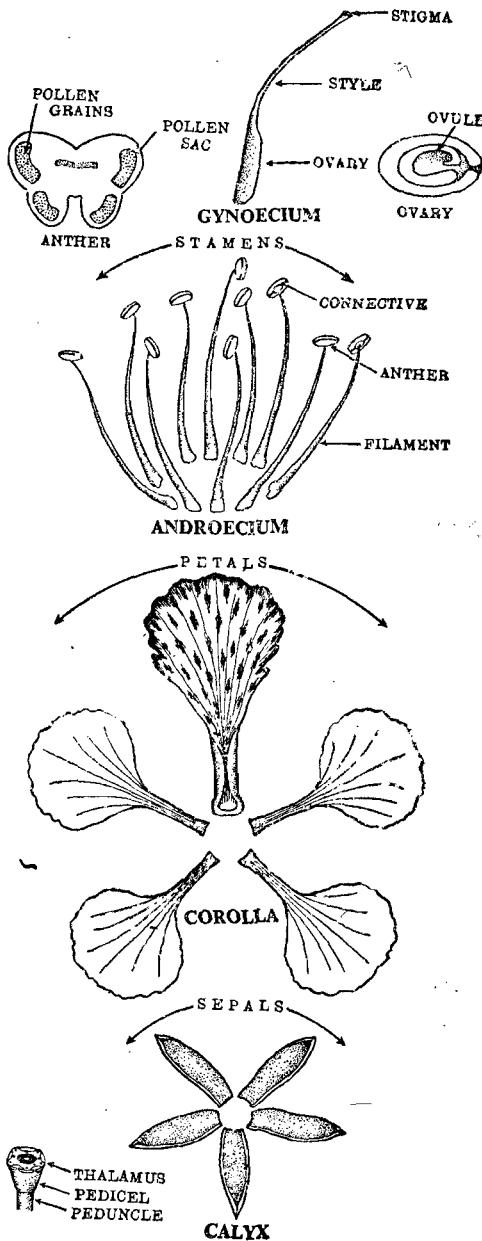

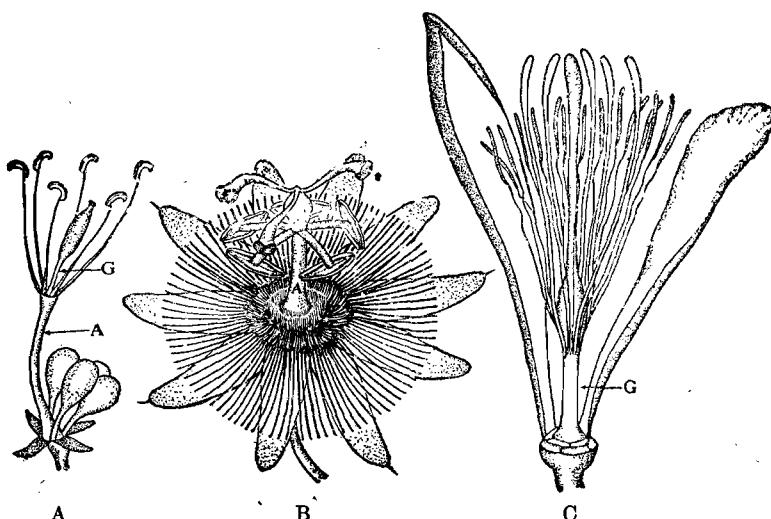

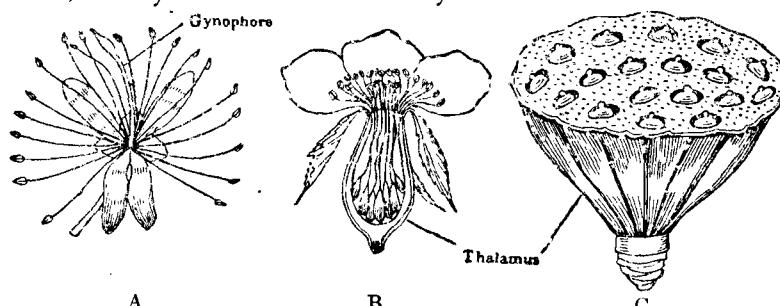

FIG. 156. Flower of gold mohur (*Delonix regia*) dissected out.

Thalamus. **Nature of the Thalamus.** The thalamus (see fig. 155), is the suppressed swollen end of the flower-axis on which are inserted the floral leaves, viz. sepals, petals, stamens

Thalamus. FIG. 157. A, flower of *Gynandropsis*; B, passion-flower; C, flower of *Pterospermum* (with the staminal tube adnate to gynophore). A, androphore; G, gynophore.

and carpels. In most flowers this thalamus is exceedingly short; but in a few cases it becomes elongated, and then it shows distinct nodes and internodes. Thus the internode between the calyx and the corolla may be elongated; this, however, is very rare. More commonly the internode between the

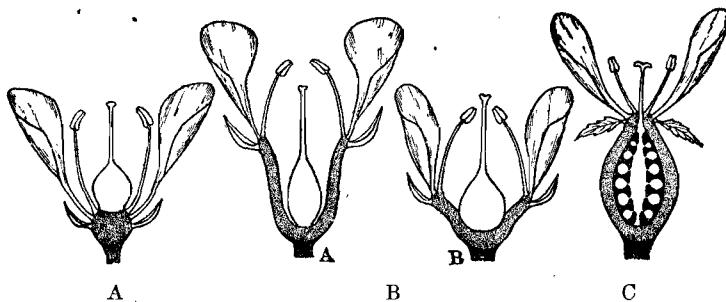

Thalamus (contd.). FIG. 158. A, flower of *Capparis*; B, rose (in section); C, lotus.

corolla and the androecium is considerably elongated, and is known as the **androphore** (*andros*, male), as in *Gynandropsis* (fig. 157A) and passion-flower (fig. 157B). In *Capparis* (fig. 158A),

Gynandropsis (fig. 157A) and *Pterospermum* (B. MOOCH-KANDA; H. KANAK-CHAMPA—fig. 157C) the axis between the androecium and the gynoecium is elongated, and is known as the **gynophore** (*gyne*, female). It is to be noted that in *Gynandropsis* (fig. 157A) both androphore and gynophore develop and they are together known as the **gynandrophore**. In *Magnolia* (B. DULEE-CHAMPA) and *Michelia* (B. CHAMPA; H. CHAMPAK) the thalamus is fleshy and elongated, and bears the floral leaves spirally round it. In rose (fig. 158B) it is concave and pear-shaped. The thalamus of lotus (fig. 158C) is spongy and top-shaped.

Position of Floral Leaves on the Thalamus (fig. 159). The relative positions of the floral whorls with respect to the ovary are of three kinds: **hypogyny**, **perigyny** and **epigyny**.

(1) **Hypogyny.** In a typical flower the ovary occupies the highest position on the thalamus, while the stamens, petals and sepals are separately and successively inserted below the

Position of Floral Leaves on the Thalamus. FIG. 159. A, hypogyny; B, perigyny (two types—A & B); C, epigyny.

ovary. Such a flower is said to be **hypogynous**. In this case the ovary is said to be *superior* and the rest of the floral members *inferior*. Examples are seen in mustard, brinjal, China rose, *Magnolia*, etc.

(2) **Perigyny.** In some flowers the thalamus grows upward around the ovary in the form of a cup, carrying on its rim the sepals, petals and stamens. Such flowers are said to be **perigynous**, and the ovary in them is said to be *half-inferior*. Examples are seen in rose, plum, peach, crepe flower, etc.

(3) **Epigyny.** In other flowers the thalamus grows further upward, completely enclosing the ovary and getting fused with it, and bears the sepals, petals and stamens on the top

of the ovary. Such flowers are said to be **epigynous**. The ovary in this case is said to be *inferior*, and the rest of the floral members *superior*. Examples are seen in sunflower, guava, gourd, cucumber, apple, pear, etc.

Bracts (fig. 160). Bracts are special leaves from the axil of which a solitary flower, or a cluster of flowers, arises. When a small leafy or scaly structure is present on any part of the flower-stalk (pedicel) it goes by the name of **bracteole**. Bracts vary in size, colour and duration, and are commonly of the following kinds.

(1) **Leafy Bracts**. These are green, flat and leaf-like in appearance, as in *Acalypha* (B. MUKTO-JHURI; H. KUPPI), *Adhatoda* (B. BASAK; H. ADALSA), etc.

(2) **Spathe** (A-B). This is a large, sometimes very large, commonly boat-shaped and brightly coloured bract, enclosing a cluster of flowers or even a whole inflorescence (spadix). It

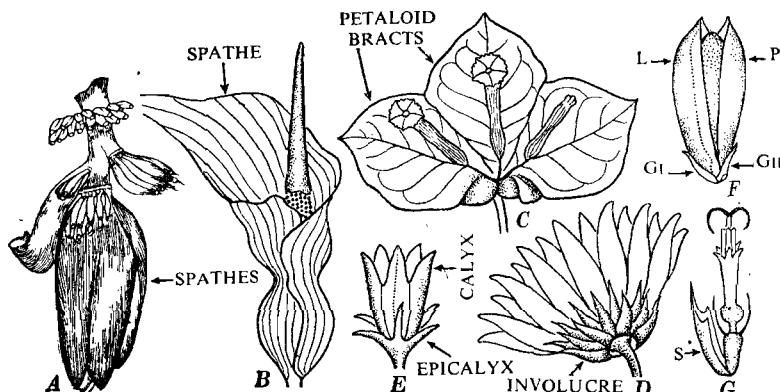

FIG. 160. Bracts and Bracteoles. A, spathes of banana; B, spathe of an aroid (*Typhonium*); C, petaloid bracts of glory of the garden; D, involucre of sunflower; E, epicalyx (bracteoles) of China rose; F, glumes of paddy grain (G_I, G_{II}, empty glumes); L, lemma or flowering glume; P, palea—a bracteole; S, scaly bracteole (S) of a central floret of sunflower.

protects the flowers while they are still young, and later attracts insects for pollination by its colour. Examples are seen in aroids, banana, palms, maize cob, etc.

(3) **Petaloid Bracts** (C). These are brightly coloured bracts looking somewhat like petals, as in glory of the garden (B. BAGAN-BILAS) and poinsettia (B. LAL-PATA).

(4) **Involucr** (D). This is a group of bracts occurring in

one or more whorls around a cluster of flowers, as in sunflower, marigold, *Cosmos*, etc. The involucre often encloses the whole inflorescence and protects the flowers when young. The bracts of the involucre are usually green, and may be free or united.

(5) **Epicalyx (E).** This is a whorl of bracteoles developing at the base of the calyx, as in China rose, cotton, lady's finger, etc.

(6) **Glumes (F).** These are special bracts, small and dry, found only in grass family and sedge family.

(7) **Scaly Bracteole (G).** This is a very small, thin, papery scale occurring at the base of the central floret of sunflower.

FLOWER IS A MODIFIED SHOOT

The following facts may be cited to prove that the *thalamus* is a modified branch; *sepals*, *petals*, *stamens* and *carpels* are modified vegetative leaves; and the *flower* as a whole a modified vegetative bud.

(1) In some flowers the thalamus becomes elongated showing distinct nodes and internodes (see figs. 157-8), as in *Gynandropsis*, passion-flower, etc. The thalamus may, therefore, be regarded as a modified branch.

(2) The thalamus sometimes shows monstrous development, i.e. after bearing the floral members it prolongs upwards and bears ordinary leaves. The thalamus thus behaves as a branch, as sometimes seen in rose (fig. 161), larkspur, pear, etc.

(3) The arrangement of sepals, petals, etc., on the thalamus is the same as that of the leaves on the stem or the branch, being either whorled, alternate (spiral) or opposite.

(4) The foliar nature of sepals and petals is evident from their similarity to leaves as regards structure, form and venation; in fact, in *Mussaenda* (fig. 162) one of the sepals becomes modified into a distinct white or coloured leaf. But stamens and carpels are unlike leaves in all respects. Their homology with leaves can be made out from certain flowers. Thus water

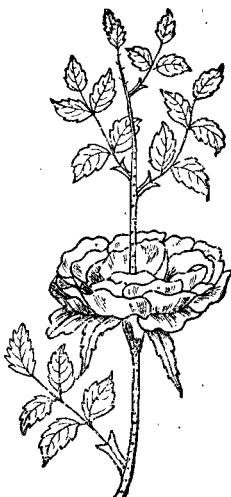

FIG. 161. Rose showing monstrous development of the thalamus.

lily (figs. 163-4) shows a gradual transition from sepals to petals and from petals to stamens. The cultivated rose shows many petals; while in wild rose there are only five. The explanation is that many stamens have gradually become modified into petals.

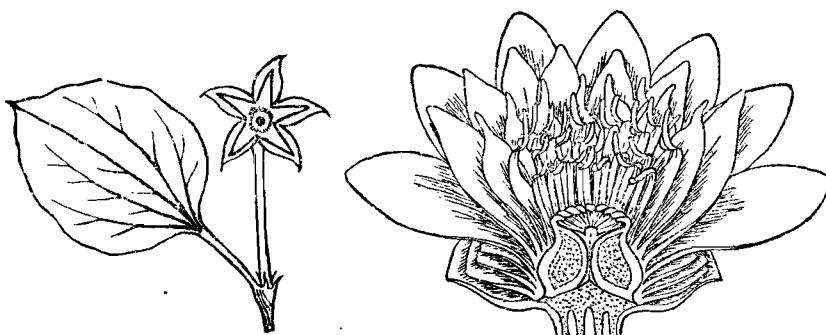

FIG. 162

FIG. 163

FIG. 162. *Mussaenda* flower with a sepal modified into a leaf. FIG. 163. Water lily flower showing transition of floral parts.

(5) The inflorescence axis normally bears flowers. Sometimes, as in American aloe (*Agave*; see fig. 363), some of the floral buds become modified into vegetative buds, called

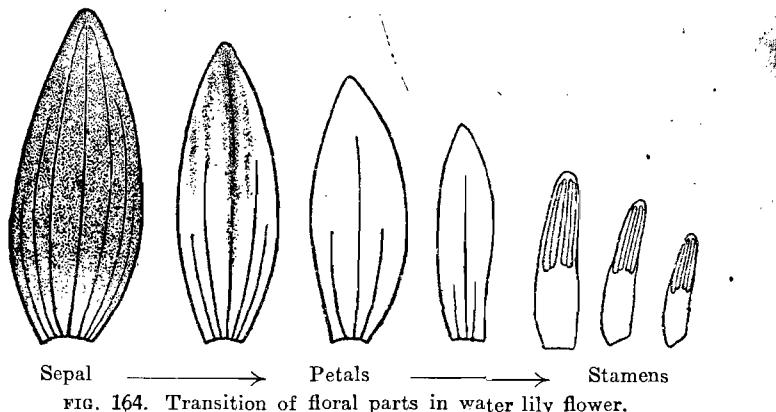

FIG. 164. Transition of floral parts in water lily flower.

bulbils, for vegetative reproduction. In pineapple also the inflorescence axis bears one or more vegetative buds or bulbils (see fig. 365) for vegetative propagation. Such bulbils thus show a reversion to ancestral forms, i.e. the forms from which they have been derived.

Symmetry of the Flower. A flower is said to be symmetrical when it can be divided into two exactly equal halves by *any* vertical section passing through the centre. Such a flower is also said to be **regular** or **actinomorphic**, e.g. mustard, potato, brinjal, *Datura*, etc. When a flower can be divided into two similar halves by *one* such vertical section only, it is said to be **zygomorphic**, e.g. pea, bean, gold mohur, *Cassia*, etc., and when it cannot be divided into two similar halves by any vertical plane whatsoever, it is said to be **irregular**.

A flower is also said to be symmetrical when its whorls (often leaving out the gynoecium) have an equal number of parts or when the number in one whorl is a multiple of that of another. Such a symmetrical flower is said to be **trimerous** when the number of parts in each whorl is 3 or any multiple of it, as mostly in monocotyledons, and **pentamerous** when the number is 5 or any multiple of it, as mostly in dicotyledons.

(1) CALYX

Calyx is the first or the lowermost whorl of the flower, and consists of a number of **sepals**. It is usually green (*sepaloid*), but sometimes it becomes coloured (*petaloid*), as in gold mohur, dwarf gold mohur and garden nasturtium. It varies in shape, size and colour ; it may be **regular**, **zygomorphic**, or **irregular**. The sepals may remain free from each other or they may be united together ; in the former case the calyx is said to be **polysepalous** (*polys*, many), as in mustard, radish, etc. ; and in the latter it is **gamosepalous** (*gamo*, united), as in brinjal, chilli, China rose, etc. The calyx is sometimes altogether absent from a flower, or it may be modified into *scales*, as in sunflower, marigold, etc., or into *pappus* (see fig. 236A), as in *Tridax* and many other plants of sunflower family. In *Mussaenda* (H. BEBINA— see fig. 162) one of the sepals becomes large, leafy and perfectly white or brightly coloured.

Functions. (1) *Protection*, as in most flowers. (2) *Assimilation*, when green in colour. (3) *Attraction*, when coloured and showy. (4) *Special function*, when modified into pappus (see fig. 236A) ; the pappus is persistent in the fruit and helps its distribution by the wind.

Duration. The calyx may fall off as soon as the floral bud opens, as in poppy. More commonly it falls off with the corolla when the flower withers ; it is then said to be **deciduous**.

Sometimes it persists and adheres to the fruit ; then it is said to be **persistent**. A persistent calyx may remain green, as in brinjal, or it may assume a withered appearance, as in cotton, or it may continue to grow and become fleshy, as in *Dillenia* (B. & H. CHALTA).

(2) COROLLA

Corolla is the second whorl of the flower, and consists of a number of **petals**. The petals are often brightly coloured and sometimes scented, and then their function is to attract insects for *pollination* ; they are rarely sepaloid. In the bud stage of the flower the corolla encloses the essential organs, namely, stamens and carpels, and protects them from external heat and rain.

Like the calyx, the corolla may also be **regular**, **zygomorphic** or **irregular**. Like the calyx again, the corolla may be **gamopetalous** or **polypetalous**, according as the petals are united or free. In the former case the petals may be united partially or wholly. In the polypetalous corolla each petal may sometimes be narrowed below, forming a sort of stalk, known as the *claw*, and expanded above ; this expanded portion is called the *limb*, as in mustard, radish, etc.

Forms of Corollas. The various forms of corollas may be studied under the following four main heads :

I. REGULAR AND POLYPETALOUS

(1) **Cruciform** (fig. 165). The cruciform corolla consists of four free petals (each differentiated into a claw and a limb) arranged in the form of a cross, as in mustard family, e.g. mustard, radish, cabbage, cauliflower, candytuft, etc.

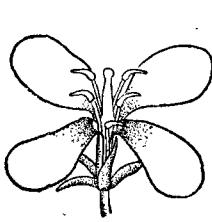

FIG. 165

Forms of Corollas. FIG. 165. Cruciform.

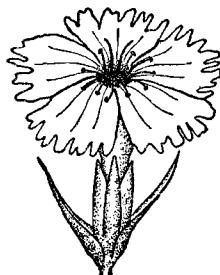

FIG. 166

FIG. 166. Caryophyllaceous.

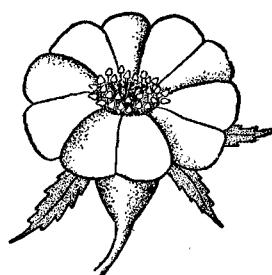

FIG. 167

FIG. 167. Rosaceous.

(2) **Caryophyllaceous** (fig. 166). This form of corolla consists of five petals with comparatively long claws, and the limbs of the petals are placed at right angles to the claws, as in pink (*Dianthus*).

(3) **Rosaceous** (fig. 167). This form consists of five petals with very short claws or none at all, and the limbs spread regularly outwards, as in rose, tea, prune, etc.

II. REGULAR AND GAMOPETALOUS

(1) **Bell-shaped** (fig. 168). When the shape of the corolla resembles that of a bell, as in gooseberry, bell flower, wild mangosteen (B. GAB ; H. KENDU), etc., it is said to be campanulate.

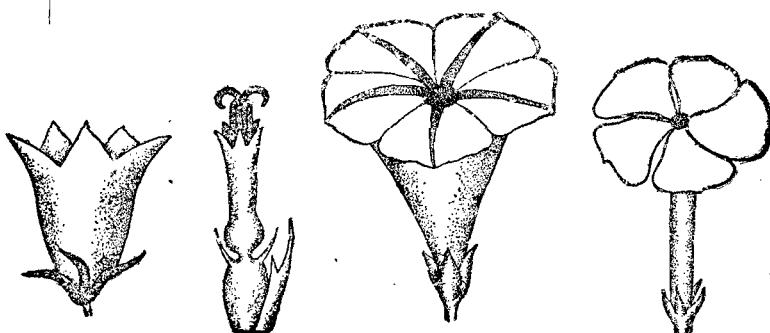

FIG. 168

FIG. 169

FIG. 170

FIG. 171

Forms of Corollas (contd.). FIG. 168. Bell-shaped. FIG. 169. Tubular.
FIG. 170. Funnel-shaped. FIG. 171. Rotate.

(2) **Tubular** (fig. 169). When the corolla is cylindrical or tube-like, that is, more or less equally expanded from base to apex, as in the central florets of sunflower, marigold, *Cosmos*, etc., it is said to be tubular.

(3) **Funnel-shaped** (fig. 170). When the corolla is shaped like a funnel, that is, gradually spreading outwards from a narrow base, as in *Datura*, water bindweed (B. & H. KALMI-SAK), railway creeper, morning glory, yellow oleander, etc., it is said to be funnel-shaped.

(4) **Rotate or Wheel-shaped** (fig. 171). When the tube of the corolla is comparatively short and its limb is at a right angle to it, the corolla having more or less the appearance of a wheel, as in night jasmine, periwinkle, etc., it is said to be rotate.

III. ZYGMORPHIC AND POLYPETALOUS

(1) **Papilionaceous** or **Butterfly-like** (fig. 172). The general appearance is like that of a butterfly. It is composed of five petals, of which the outermost one is the largest and known as the **standard** or **vexillum**, the two lateral ones are known as

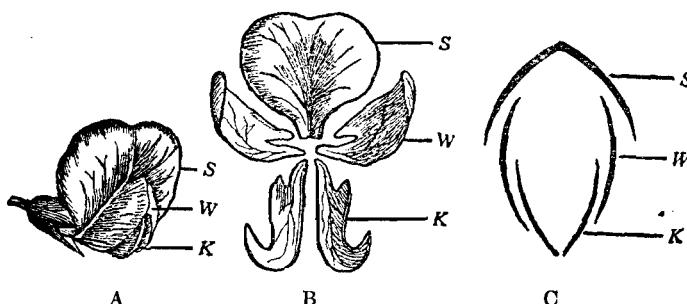

FIG. 172. A, papilionaceous flower of pea; B, petals of the same opened out; C, vexillary aestivation of papilionaceous corolla.
S, standard or vexillum; W, wing; K, keel.

the **wings** or **alae**, and the two innermost ones are the smallest and are together known as the **keel** or **carina**. These two are apparently united to form a boat-shaped cavity. Examples are found in pea family, e.g. pea (fig. 172), bean, gram, butterfly pea (B. APARAJITA ; H. APARAJIT), etc.

IV. ZYGMORPHIC AND GAMOPETALOUS

(1) **Bilabiate** or **Two-lipped** (fig. 173). In this form the limb of the corolla is divided into two portions or lips—the upper

FIG. 173
Forms of Corollas (contd.).
FIG. 173. Bilabiate. FIG. 174. Personate. FIG. 175. Ligulate.

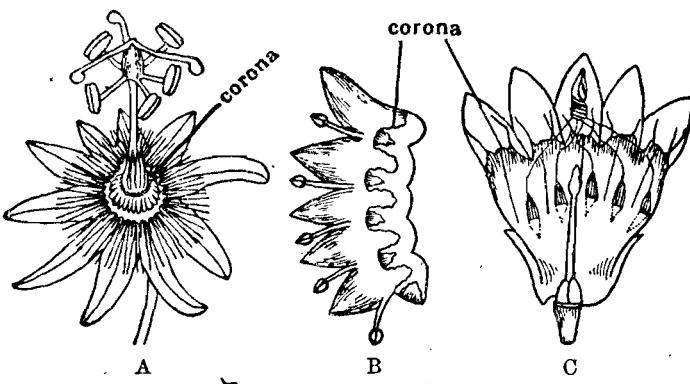

and the lower, with the mouth gaping wide open. Examples may be seen in sacred basil (*Ocimum*; B. & H. TULSI), *Leo-*

nurus (B. DRONA; H. HALKUSHA), *Adhatoda* (B. BASAK; H. ADALSA), etc.

(2) **Personate** or **Masked** (fig. 174). This is also two-lipped like the previous one, but in this case the lips are placed so near to each other as to close the mouth of the corolla, as in snapdragon, *Lindenbergia*, etc. Insects sit on the lower lip and push open the mouth of the corolla.

(3) **Ligulate** or **Strap-shaped** (fig. 175). When the corolla forms into a short, narrow tube below, but is flattened above like a strap, as in the outer florets of sunflower, marigold, *Cosmos*, etc., it is said to be ligulate.

Corona (fig. 176). Sometimes, by a transverse splitting of the corolla, an additional whorl may be formed at its throat. This additional whorl may be made up of lobes, scales or hairs, free or united, and is known as **corona** (*crown*). The corona

Corona. FIG. 176. A, passion-flower; B, dodder; C, oleander.

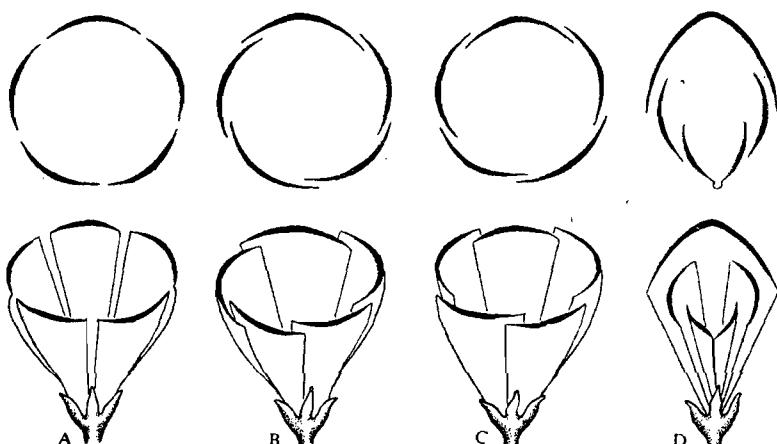

may be well seen in passion-flower (A), dodder (B), and oleander (C). A beautiful, cup-shaped corona is seen in daffodil. The corona adds to the beauty of the flower and is thus an adaptation to attract insects for pollination.

Aestivation (fig. 177). The mode of arrangement of the sepals or of the petals, more particularly the latter, in a floral bud with respect to the members of the same whorl (calyx or corolla) is known as **aestivation**. Aestivation is an important character from the view-point of classification of plants, and may be of the following types.

(1) **Valvate** (A), when the members of a whorl are in contact with each other by their margins, or when they lie very

close to each other, but do not overlap, as in custard-apple, madar, *Artabotrys* (B. & H. KANTALI-CHAMPA), etc.

(2) **Twisted** or **Contorted** (B), when one margin of the sepal or the petal overlaps that of the next one, and the other margin is overlapped by the third one, as in China rose,

Aestivation of Corolla. FIG. 177. *A*, valvate; *B*, twisted; *C*, imbricate; *D*, vexillary. *Top*, corolla in transsection; *bottom*, floral bud cut transversely.

cotton, etc. Twisting of the petals may be clockwise or anti-clockwise. In China rose both types (clockwise and anticlockwise) are found.

(3) **Imbricate** (C), when one of the sepals or petals is internal being overlapped on both the margins, and one of them is external and each of the remaining ones is overlapped on one margin and it overlaps the next one on the other margin, e.g. *Cassia*, gold mohur, dwarf gold mohur, etc.

(4) **Vexillary** (D), when there are five petals, of which the posterior one is the largest and it almost covers the two lateral petals, and the latter in their turn nearly overlap the two anterior or smallest petals. Vexillary aestivation is universally found in all papilionaceous corollas, as in pea, bean, butterfly pea, rattlewort, etc.

(3) ANDROECIUM

Androecium (*andros*, male) is the third or the male reproductive whorl of the flower, and is composed of a number of

stamens. Each stamen consists of **filament**, **anther** and **connective** (fig. 178). The filament is the slender stalk of the stamen, and the anther is the expanded head borne by the

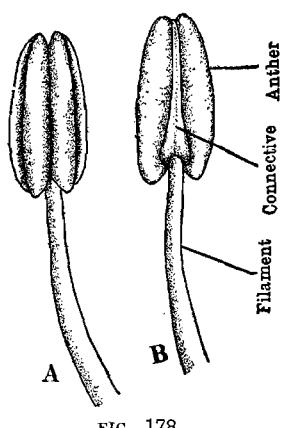

FIG. 178

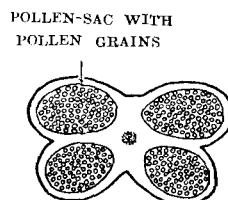

FIG. 179.

FIG. 178. Two stamens. *A*, face of the anther showing four pollen-sacs; *B*, back of the anther showing connective.

FIG. 179. Anther in section.

filament at its tip. Each anther consists usually of two lobes connected together by a sort of midrib known as the **connective**. Each lobe contains within it two chambers or loculi, called the **pollen-sacs**; thus there are altogether four loculi in

FIG. 180.
Pollen grains.
A, an entire grain;
B, a grain in section showing tube-nucleus (bigger one) and generative nucleus (smaller one).

FIG. 181.
Growth of the pollen-tube.

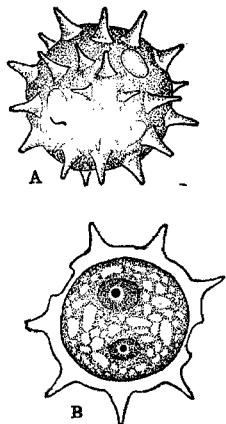

FIG. 180

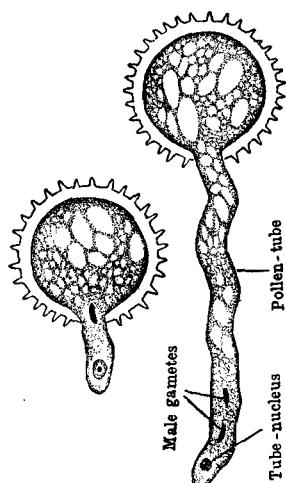

FIG. 181

each anther (fig. 179), sometimes two or even one. Within each pollen-sac there is a fine, powdery or granular mass of cells, called the **pollen grains**. Sometimes pollen grains are

produced in large quantities, and when the anther bursts they

are scattered by the wind like particles of dust, as seen in pine, palms, screwpine, maize, etc. A **sterile stamen**, i.e. the one not bearing pollen grains, is called a **staminode**, as in noon flower. In madar and orchids the pollen cells are not free but become united into a mass known as **pollinium** (fig. 182).

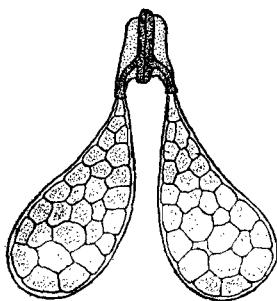

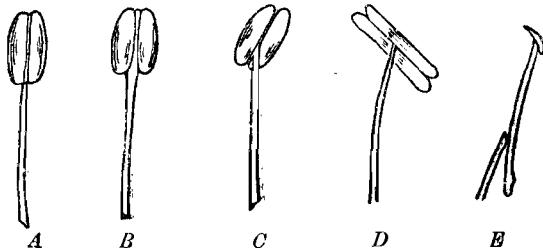

FIG. 182. Pollinia of madar (*Calotropis*). These are the male productive bodies of a flower, and are contained in the pollen-sacs.

They are very minute in size, varying from 10 to 200 microns, and are like particles of dust. Each pollen grain consists of a single microscopic cell, and possesses two coats: the **exine** and the **intine**. The exine is a tough, cutinized layer which is often provided with spinous outgrowths or markings of different patterns, sometimes smooth. The intine, however, is a thin, delicate, cellulose layer lying internal to the exine. In pine the pollen grain is provided with two distinct wings. When the pollen grain germinates the intine grows out into a tube, called the **pollen-tube** (fig. 181), through some definite thin and weak slits or pores, called **germ pores**, present in the exine (fig. 180). The pore may be covered by a distinct lid which is pushed open by the growth of the intine. Two nuclei may be seen in the pollen grain, of which the larger one is known as the vegetative nucleus or **tube-nucleus** and the smaller one the **generative nucleus**. As the pollen-tube grows it carries with it at its apex the tube-nucleus and the generative nucleus. The generative nucleus soon divides into two male reproductive units called **male gametes**. The tube-nucleus becomes disorganized.

Attachment of the Filament to the anther (fig. 183). The anther is said to be (A) **basifixed** or **innate**, when the filament is attached to the base of the anther, as in mustard, radish, sedge, water lily, etc.; (B) **adnate**, when the filament runs up the whole length of the anther from the base to the apex, as in *Michelia*, *Magnolia*, etc.; (C) **dorsifixed**, when it is attached to the back of the anther, as in passion-flower; and (D) **versatile**, when it is attached to the back of the anther at one

point only so that the latter can swing freely in the air, as in

FIG. 183.
A, basifixed;
B, adnate;
C, dorsified;
D, versatile;
E, elongated
 connective
 of sage (*Salvia*)
 separating the
 two anther-lobes.

grasses, palms, spider lily, etc. (*E*) In sage (*Salvia*) the filament is attached to the elongated connective separating the two anther-lobes, of which the upper one is fertile and the lower one sterile. The connective plays freely on the filament.

Cohesion and Adhesion. The terms 'adhesion', 'adnate', and 'adherent' are used to designate the union of members of different whorls, e.g. petals with stamens, or stamens with carpels; and 'cohesion', 'connate', and 'coherent' to designate the union of members of the same whorl, e.g. stamens with each other, and carpels with each other.

Cohesion of Stamens. Stamens may either remain free or they may be united (coherent). There may be different degrees of cohesion of stamens, and these may be referred to as the (*a*) adelphous condition when the stamens are united by their filaments only, the anthers remaining free; or (*b*) syngenesious condition when the stamens are united by their anthers only, the filaments remaining free. Accordingly the following types are seen.

(i) **Monadelphous Stamens** (*monos*, single; *adelphos*, brother). When all the filaments are united together into a

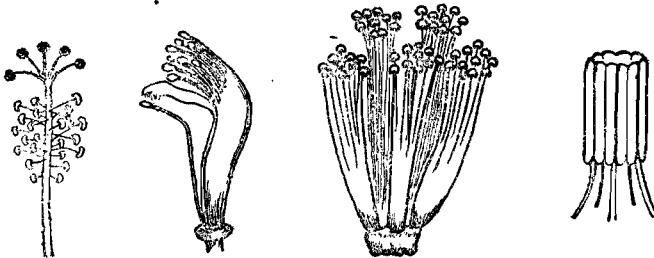

FIG. 184

FIG. 185

FIG. 186

FIG. 187

Cohesion of Stamens. Fig. 184. Monadelphous. Fig. 185. Diadelphous. Fig. 186. Polyadelphous. Fig. 187. Syngenesious.

single bundle but the anthers are free, the stamens are said to be monadelphous (fig. 184), as in China rose family, e.g. China

rose, lady's finger, cotton, etc. In them the filaments are united into a tubular structure, called staminal tube, ending in free anthers.

(2) **Diadelphous Stamens** (*di*, two). When the filaments are united into two bundles, the anthers remaining free, the stamens are said to be diadelphous (fig. 185), as in pea family, e.g. pea, bean, gram, butterfly pea, coral tree, rattlewort, etc. In them there are altogether ten stamens of which nine are united into one bundle and the tenth one is free.

(3) **Polyadelphous Stamens** (*polys*, many). When the filaments are united into a number of bundles—more than two, but the anthers are free, the stamens are said to be polyadelphous (fig. 186), as in silk cotton tree, castor, lemon, pummelo or shaddock, etc.

(4) **Syngenesious Stamens** (*syn*, together or united; *genes*, producing). When the anthers are united together into a bundle or tube, but the filaments are free, the stamens are said to be syngenesious (fig. 187), as in sunflower family, e.g. sunflower, marigold, safflower, *Tridax*, etc.

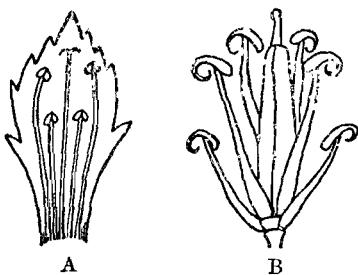

Adhesion of Stamens. When the stamens adhere to the corolla wholly or partially by their filaments, anthers remaining free, they are said to be (1) epipetalous, as in *Datura*, tobacco, potato, *Ixora* (B. RANGAN ; H. GOTAGANDHAL), sunflower, etc. Most of the flowers with a gamopetalous corolla have epipetalous stamens. When the stamens adhere to the carpels, either throughout their whole length or by their anthers only, they are said to be (2) gynandrous, as in madar (B. AKANDA ; H. AK), orchids, etc.

Length of Stamens (fig. 188). The stamens of a flower may be

of the same length, or their lengths may vary without any definite relation to each other. But in some cases there is a definite relation between short and long stamens. Thus in sacred basil (B. & H. TULSI), *Leonurus* (B. DRONA ; H. HAL-KUSHA), *Leucas* (B. SWET-DRONA ; H. CHOTA-HALKUSHA), etc., there are four stamens, of

Length of Stamens. FIG. 188.
A, didynamous; B, tetradynamous.

which two are long and two short; such stamens are said to

be (1) **didynamous** (*di*, two; *dynamis* strength). In mustard family, e.g. mustard, radish, turnip, rape, etc., there are six stamens, of which four are long and two short; such stamens are said to be (2) **tetradynamous** (*tetra*, four).

(4) GYNOECIUM OR PISTIL

Gynoecium (*gyne*, female) or pistil is the fourth or the female reproductive whorl of the flower, and is composed of one or more **carpels** which are modified leaves meant

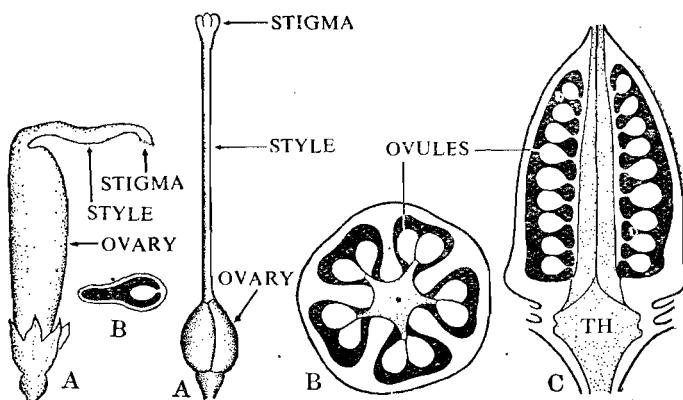

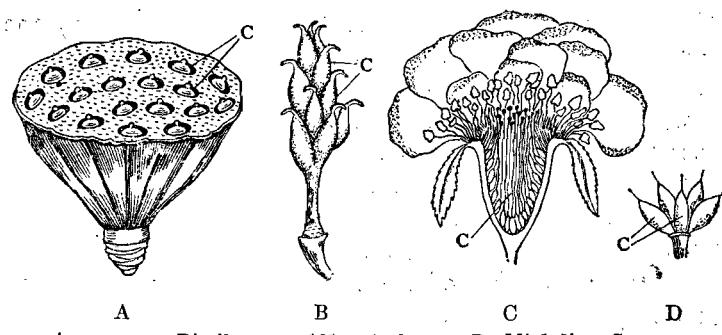

FIG. 189

FIG. 190

Pistil. FIG. 189. A, a simple pistil of pea; B, one-chambered ovary of the same. FIG. 190. A, a syncarpous pistil; B, ovary of the same in transection; C, ovary of the same in longi-section

to bear ovules (fig. 190 b-c) and an embryo-sac within each ovule (see fig. 193). When the pistil is made of only one carpel

Apocarpous Pistil. FIG. 191. A, lotus; B, *Michelia*; C, rose; D, stonecrop (*Sedum*). C, carpels.

as in the flowers of pea, bean, gold mohur, sensitive plant, etc., it (the pistil) is said to be **simple** or monocarpellary (fig. 189), and when it is made of two or more carpels, the pistil is said to be **compound** or polycarpellary. In a compound pistil the carpels may be free (*apocarpous*) with as many ovaries as the number of carpels (fig. 191), as in lotus, *Michelia* (B. CHAMPA; H. CHAMPAKA), rose, stonecrop (*Sedum*—a pot herb), *Magnolia* etc., or the carpels may be united together into one ovary (*syncarpous*; fig. 190); the latter is mere common. Each pistil consists of three parts—**stigma**, **style** and **ovary** (fig. 190 A). The small rounded or lobed head of the pistil is known as the **stigma**; the slender stalk supporting the stigma is called the **style**; and the swollen basal part of the pistil which forms one or more chambers is termed the **ovary**. The ovary contains one or more little, roundish or oval, egg-like bodies which are the rudiments of seeds and are known as the **ovules**. Each ovule encloses a large oval cell known as the **embryo-sac** (see fig. 193). The ovary gives rise to the fruit and the ovules to the seeds. A functionless or sterile pistil is called a **pistillode**, as in the ray floret of sunflower.

Carpels in Syncarpous Pistil. In a syncarpous pistil it is often difficult to determine the number of carpels. To obviate this difficulty the following points should be noted: 1st, the number of stigmas or of stigmatic lobes; 2nd, the number of styles; 3rd, the number of lobes of the ovary; 4th, the number of chambers (loculi) of the ovary; 5th, the number of placentae in the ovary; and 6th, the number of groups of ovules in the ovary. It is seen that in most cases the number of parts, as mentioned above, corresponds to the number of carpels making up the syncarpous pistil.

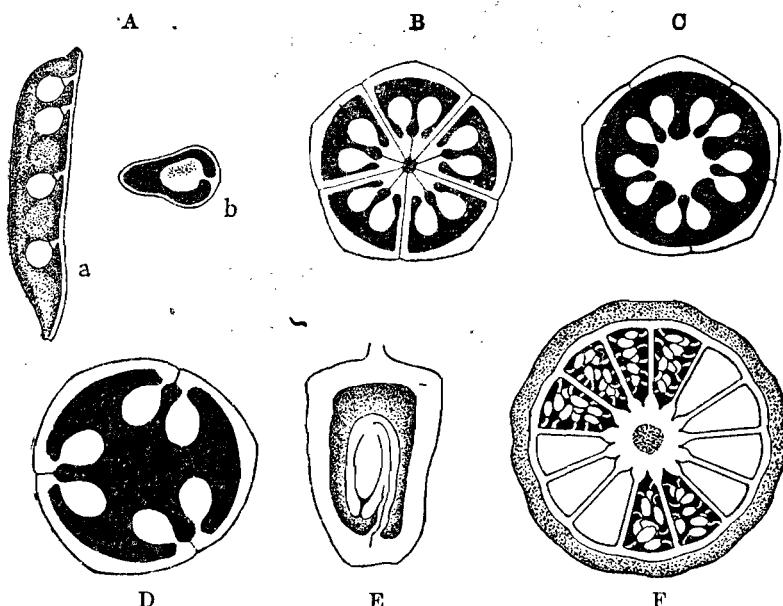

The Ovary. The ovary is the closed chamber formed by the union of margins of one or more carpels (which are regarded as metamorphosed leaves). In the simple or apocarpous pistil the carpel folds along the mid-rib and the two margins meet and fuse together forming the ovary (fig. 189). In the syncarpous pistil the carpels likewise meet by their respective margins and form the ovary. If then the margins extend inwards and meet in the centre the ovary becomes two- or more-chambered according to the number of carpels (fig. 190). If, however, the margins only meet at the circumference but do not grow further the ovary remains one-chambered (fig. 192 D). The junc-

tion of two margins of one or more carpels is called the *ventral suture*, and the mid-rib along which each carpel folds is called the *dorsal suture*. The placenta normally develops along the ventral suture.

PLACENTATION

Placenta is a ridge of tissue in the inner wall of the ovary, bearing one or more ovules, and the manner of distribution of the placentae within the ovary is called **placentation**. The placentae most frequently develop on the margins of carpels either along their whole line of union, called the **suture**, or at their base or apex.

Types of Placentation (fig. 192). In the simple ovary (of one carpel) there is one common type of placentation, known as **marginal**, and in the compound ovary (of two or more carpels united together) placentation may be **axile**, **parietal**, **central**, **free-central**, **basal**, or **superficial**.

Types of Placentation. FIG. 192. A, marginal; a, longitudinal section; b, transverse section; B, axile; C, central; D, parietal; E, basal; F, superficial.

(i) **Marginal.** In marginal placentation (A) the ovary is one-chambered and the placenta develops along the junction of the

two margins of the carpel, called the *ventral suture*, as in pea, gram, gold mohur, *Cassia*, sensitive plant, etc.)

(2) **Axile.** In the axile placentation (B) the ovary is many-chambered—usually as many as the number of carpels—and the placentae bearing the ovules develop from the central axis corresponding to the confluent margins of carpels, and hence the name axile (lying in the axis), as in lemon, orange, China rose, tomato, potato, etc.

(3) **Central.** In the central placentation (C) the septa or partition walls in the young ovary soon break down so that the ovary becomes one-chambered and the placentae bearing the ovules develop all round the central axis, as in pink family, e.g. pink (*Dianthus*), *Polycarpon* (B. GIMA-SAK), soapwort, etc. Remnants of partition walls may often be seen.

(4) **Parietal** (*parietis*, wall). In the parietal placentation (D) the ovary is one-chambered, and the placentae bearing the ovules develop on the inner wall of the ovary corresponding to the confluent margins of carpels. There are as many placentae as the number of carpels, as in papaw, poppy, prickly poppy, orchids, etc. In mustard family, e.g. mustard, radish, rape, etc., the placentation is also parietal but here the ovary becomes 2-chambered due to the development of a *false* partition wall called *replum*.

(5) **Basal.** In the basal placentation (E) the ovary is unilocular and the placenta develops directly on the thalamus, and bears a single ovule at the base of the ovary. This is seen in sunflower family, e.g. sunflower, marigold, *Cosmos*, etc.

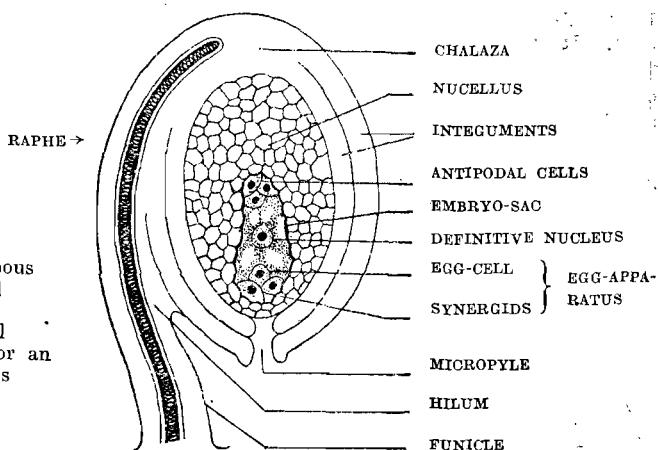

(6) **Superficial.** In the superficial placentation (F) the ovary is multilocular, carpels being numerous, as in the axile placentation, but the placentae in this case develop all round the inner surfaces of the partition walls, as in water lily.

THE OVULE

Structure of the Ovule. Each ovule (fig. 193) is attached to the placenta by a slender stalk known as (1) the **funicle**. The point of attachment of the body of the ovule to its stalk or funicle is known as (2) the **hilum**. In the inverted ovule, as shown in fig. 193, the funicle continues beyond the hilum alongside the body of the ovule forming a sort of ridge; this ridge is called (3) the **raphe**. Through the raphe food is carried to the nucellus. The distal end of the raphe or the funicle which is the junction of the integuments and the nucellus is called (4) the

chalaza. The main body of the ovule is called (5) the **nucellus**, and it is surrounded by *two* coats (or only one in some) termed (6) the **integuments**. A small opening is left at the apex of the integuments; this is called (7) the **micropyle**. Lastly, there is a large, oval cell lying embedded in the nucellus towards the micropylar end; this is (8) the **embryo-sac**, that is, the sac that bears the embryo, and is the most important part of the ovule.

FIG. 193.
An anatropous
or inverted
ovule in
longitudinal
section. For an
orthotropous
or straight
ovule see
FIG. 195B.

Parts and Functions of the Embryo-sac (figs. 193 & 1941). In the mature embryo-sac a group of three cells, each surrounded by a very thin wall, may be seen always lying towards the micropyle; this group is called (1) the **egg-apparatus**. One cell of this group is the female gamete known as (a) the **egg-cell or ovum**, and the other two known as (b) the **synergids** (*syn*, together; *ergein*, to work) or co-operating cells or help cells. The egg-cell on fertilization, i.e. on fusion with a male gamete of the pollen-tube, gives rise to the embryo; this is the most important function of the embryo-sac. The synergids may aid in the process of fertilization by guiding the two male gametes of the pollen-tube to the egg-cell and the definitive nucleus. As soon as their function is over they become disorganized. At the opposite end of the embryo-sac there is another group of three cells known as (2) the **antipodal cells**, each often surrounded by a very thin wall. These have no definite function; so sooner or later they get disorganized. Somewhere in the middle of the embryo-sac there is a distinct nucleus known as (3) the **definitive nucleus** which is the fused

product of the two polar nuclei i.e. the two nuclei coming from the two poles or ends of the embryo-sac (fig. 194 G-I). After a second fusion with the remaining male gamete it forms the **endosperm nucleus** which may soon grow into the **endosperm** of the seed (see pp. 19-20); this is the second important function of the embryo-sac.

Development of Embryo-sac (fig. 194). At a very early stage in the life of the ovule a particular cell of it—the mother cell of the embryo-sac—enlarges (A-B). It divides twice to produce a row of four megasporocytes (C). The upper three degenerate and appear as dark caps (D), while the lowest one functions. It enlarges and finally forms the embryo-sac; its nucleus divides thrice to give rise to eight nuclei, four at each end or pole (E-G). Then one nucleus from each pole moves inwards (G), and the two polar nuclei fuse together, somewhere in the middle (H) forming the definitive nucleus, also called the fusion nucleus (I). A fully developed embryo-sac consists of the parts as described before.

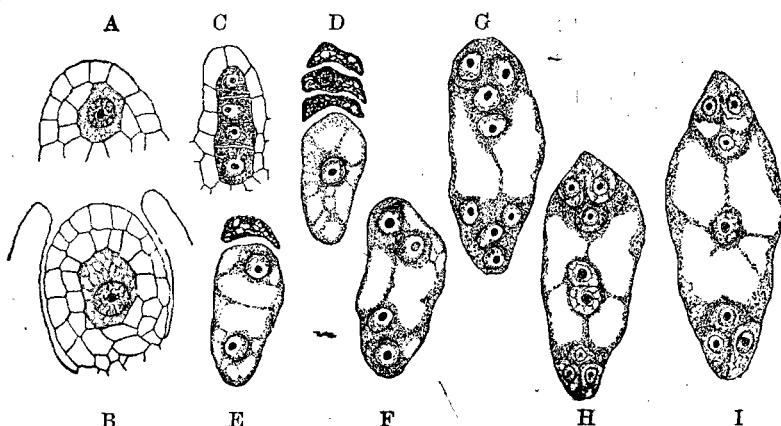

FIG. 194. Development of the embryo-sac. A, B, C, etc., are stages in its development; I, fully developed embryo-sac.

Forms of Ovules (fig. 195). The ovule is said to be (1) **orthotropous** (*orthos*, straight; *tropos*, a turn) or **straight** (B) when the ovule is erect or straight so that the funicle, chalaza and

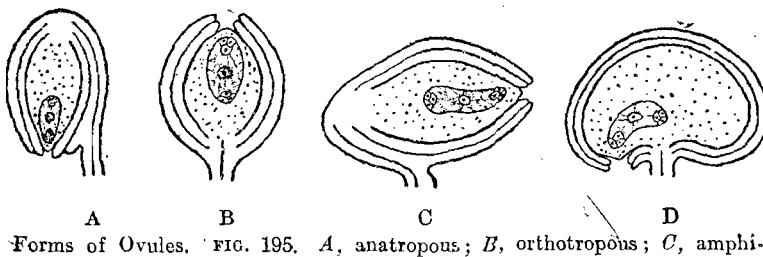

FIG. 195. A, anatropous; B, orthotropous; C, amphitropous; D, campylotropous.

micropyle lie in one and the same vertical line, as in *Polygonum*, sorrel, betel, etc.; (2) **anatropous** (*and*, backwards or up) or **inverted** (A) when the ovule bends back alongside the funicle so that the micropyle lies close to the hilum; the micropyle and the chalaza, but not the funicle, lie in the same straight line; this is the commonest form of ovule, (3) **amphitropous** (*amphi*, on both sides) or **transverse** (c) when the ovule is placed transversely at a right angle to its stalk or funicle, as in duckweed; and **campylotropous** (*kampylos*, curved) or **curved** (d) when the transverse ovule is bent round like a horse-shoe so that the micropyle and the chalaza do not lie in the same straight line, as in four o'clock plant, *Polycarpon* (B. GIMA-SAK), etc.

Features used to describe a Flower

Flower: solitary or in inflorescence (mention the type); sessile or stalked; complete or incomplete; unisexual or bisexual; regular, zygomorphic or irregular; hypogynous, epigynous or perigynous; nature of bracts and bracteoles, if present; shape of the flower, its colour and size.

Calyx: polysepalous or gamosepalous; number of sepals or of lobes; superior or inferior; aestivation; shape, size and colour.

Corolla: polypetalous or gamopetalous; number of petals or of lobes; superior or inferior; aestivation; shape, size, colour and scent; corona or any special feature. (When there is not much difference between the calyx and the corolla the term **perianth** should be used; it may be sepaloid or petaloid; polyphyllous or gamophyllous.)

Androecium: number of stamens—definite (ten or less) or indefinite (more than ten); free or united; nature of cohesion—monadelphous, diadelphous, polyadelphous, syngenesious or synandrous; nature of adhesion—epipetalous or free from the petals; whether alternating with the petals (or corolla-lobes) or opposite them; length of stamens—general length; inserted or exerted; didynamous or tetrodynamous; position of stamens—hypogynous, perigynous or epigynous; attachment of the anther.

Gynoecium or Pistil: number of carpels; syncarpous or apocarpous; nature of style—long or short; stigmas—simple, lobed or branched; their number and nature—smooth or papillose; ovary—superior or inferior; number of lobes; number of chambers (loculi); nature of placentation; number and form of ovules in each loculus of the ovary.

Description of Pea Flower (see fig. 452). **Flowers** axillary—either solitary or in a few-flowered raceme, zygomorphic, complete, bisexual, hypogynous, and papilionaceous. **Calyx**—sepals 5, unequal, united into an oblique tube, 5-lobed. **Corolla**—petals 5, free, papilionaceous, with vexillary aestivation—the outermost petal known as the *standard* is broad, the lateral two are the *wings*, enclosing the two innermost ones—the *keel*. **Androecium**—stamens ten, (9)+1, diadelphous. **Gynoecium**—carpel 1; ovary subsessile, one-chambered and few-ovuled; placentation marginal; style one, inflexed, bearded on the inner side.

CHAPTER 10 *Pollination*

Pollination is the transference of pollen grains from the anther of a flower to the stigma of the same flower or of another flower of the same or sometimes allied species. Pollination is of two kinds, viz. (1) **self-pollination or autogamy** (*autos*, self; *gamos*, marriage) and (2) **cross-pollination or allogamy** (*allos*, different). Self-pollination is the transference of pollen grains from the anther of a flower to the stigma of the same flower or to another flower borne by the same plant. In self-pollination only one parent plant is concerned in producing the offspring. Cross-pollination on the other hand is the transference of pollen grains from one flower to another flower borne by two separate plants of the same or allied species, irrespective of whether the flowers are bisexual or unisexual. In cross-pollination two parent plants are involved and, therefore, a mingling of two sets of parental characters takes place resulting in better offspring. Both the methods are, however, widespread in nature.

1. SELF-POLLINATION OR AUTOGAMY

Self-pollination may under natural conditions take place when both the anthers and the stigma of a bisexual flower mature at the same time (**homogamy**). It is likely then that some of the pollen grains are dropped on the stigma through the agency of insects or wind. Then again in some plants the bisexual flowers never open. They remain closed and the pollen grains may only pollinate the stigma of the same flower (**cleistogamy**), as in *Commelina bengalensis* (fig. 196). Self-pollination also takes place between two unisexual flowers borne by one and the same plant.

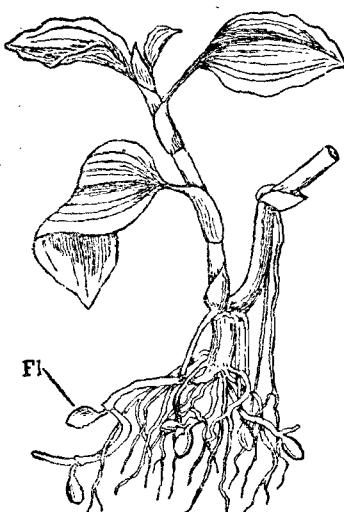

FIG. 196. *Commelina bengalensis*.
Fl., underground flower.

2. CROSS-POLLINATION OR ALLOGAMY

This is brought about by external agents which carry the pollen grains of one flower and deposit them on the stigma of another flower, the two being borne by two separate plants of the same or closely allied species. The agents are insects (bees, flies, moths, etc.), some animals (birds, snails, etc.), wind and water, and to achieve cross-pollination through them the adaptations in flowers are many and varied.

1. Entomophily (*entomon*, an insect; *philein*, to love). Pollination by insects is of very general occurrence among plants. Entomophilous or insect-loving flowers have various adaptations by which they attract insects and use them as conveyors of pollen grains from one flower to another for the purpose of pollination. Principal adaptations are **colour**, **nectar** and **scent**. There are some special adaptations also in certain flowers.

Colour. One of the most important adaptations is the **colour** of the petals. In this respect the brighter the colour and the more irregular the shape of the flower the greater is the attraction. Sometimes, when the flowers themselves are not conspicuous, other parts may become coloured and showy to attract insects. Thus in *Mussaenda* (see fig. 162) one of the sepals is modified into a large white or coloured leafy structure which serves as an 'advertisement' flag to attract insects. In some cases bracts become highly coloured and attractive, as in glory of the garden (B. BAGAN-BILAS--see fig. 160 c), poinsettia (B. LAL PATA), etc. The spathes also often become brightly coloured, as in bananas and aroids. In sunflower, marigold, etc., the head or capitulum consisting of a cluster of small florets become as a whole very attractive.

Nectar. Another important adaptation is the **nectar**. Nearly all flowers with gamopetalous corolla secrete nectar which is a positive attraction to the cleverer insects like bees. Nectar is contained in a special gland, called *nectary*, and sometimes in a special sac, or a tube-like structure called the *spur* (figs. 197-200). The nectary occurs at the base of one of the floral whorls, and as the bees collect the nectar from the nectary or the sac or the spur they incidentally bring about pollination.

Scent. The third adaption is the **scent**. Most of the nocturnal flowers are insect-loving and they emit at night a sweet scent which attracts insects from a distance. At night, when the colour fails, the scent is particularly useful in directing

the insects to the flowers. Thus nocturnal flowers are mostly

FIG. 200. Flower of balsam. 's', spur.

sweet-smelling. Common examples are night jasmine, queen of the night, jasmines, Rangoon creeper; (*B. SANDHYAMALATI*; *H. LAL-MALTI*), etc. On the other hand the stinking

smell that is emitted from the appendix of mature *Amorphophallus* inflorescence (fig. 201) is immensely liked by certain small flies (carrion-flies), and pollination is achieved through them.

The pollen grains of entomophilous flowers are either sticky or provided with spinous outgrowths. The stigma is also sticky. Pollen grains and nectar sometimes afford excellent food for certain insects. They also often visit the flowers in search of shelter from sun and rain.

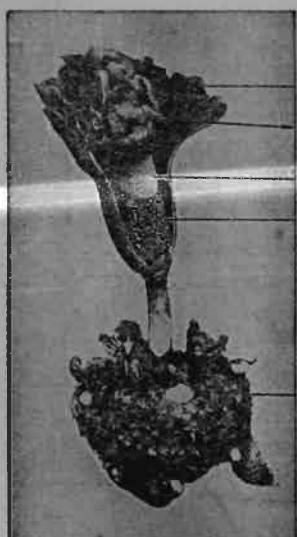

FIG. 201. Spadix of *Amorphophallus*. (B. OL; H. KANDA).

Pollination in sage (*Salvia*; FIG. 202). A very interesting case of cross-pollination by insects is seen in the flowers of this plant. In them the two anther-lobes of each stamen are widely separated by the elongated curved connective. As the insect enters the flower it pushes the sterile lower lobe. The connective swings round and the upper fertile lobe strikes the back of

the insect and dusts it with pollen grains. After the insect leaves the flower the stigma matures and bends down to receive the pollen grains from the back of another insect which has brought them from another flower.

2. Anemophily (*anemos*, wind). In some cases pollination is brought about by wind. Anemophilous or wind-loving flowers are small and inconspicuous. They are never coloured or showy. They do not emit any smell nor do they secrete any nectar. The anthers produce an immense quantity of pollen grains, wastage during transit from one

flower to another being considerable. They are also minute, light and dry, sometimes, as in pine, provided with wings. In this way the pollen grains are easily carried by the wind and distributed over a wide area, evidently helping cross-pollination. Stigmas are comparatively large and protruding, sometimes branched and often feathery. Examples are seen in maize, rice, grasses, bamboo, sugarcane, pine and several palms. (Wheat, however, is habitually self-pollinated).

Anemophily is well illustrated by maize or Indian corn plant (fig. 203). The male flowers (spikelets) of the panicle on the top produce an immense quantity of pollen grains. As the anthers burst, the pollen grains are set adrift by air-currents and many of them, particularly those brought from the neighbouring plants, are caught by the long hanging styles borne by the female flowers (spikelets) of the spadix lower down.

FIG. 203. Maize plant with male flowers in a panicle (above) and female flowers in a spadix (below). Note the long hanging styles.

3. Hydrophily (*hydor*, water). Pollination may also be brought about in some aquatic plants, particularly the submerged ones, through the medium of water, e.g. *Naias*, *Vallisneria*, *Hydrilla*, etc.

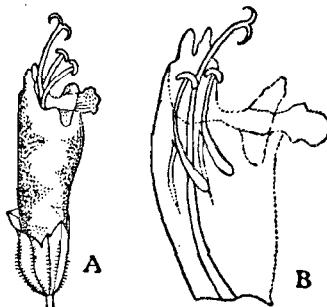

FIG. 202. Sage (*Salvia*). A, entire flower; B, showing elongated connective.

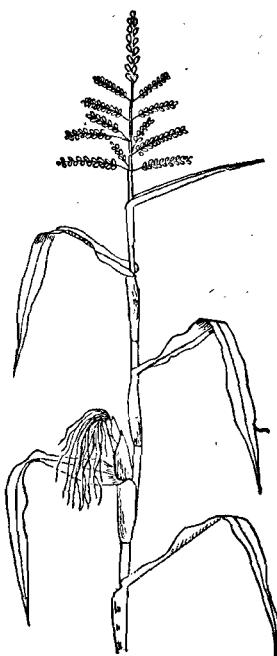

FIG. 203. Maize plant with male flowers in a panicle (above) and female flowers in a spadix (below). Note the long hanging styles.

Hydrophily may be illustrated by *Vallisneria* (fig. 204). The plant is dioecious and submerged. The minute male flowers get detached from the small spadix of the male plant and float on water. Each female flower borne on a long stalk by the female plant is brought to the level of water. Then the free-floating male flowers are set adrift towards the female flower. They come in contact with the female flower. The anthers burst and the pollen grains are distributed on the stigma of the female flower. Thus pollination is brought about. The stalk of the female flower then becomes closely coiled and the fruit develops under water.

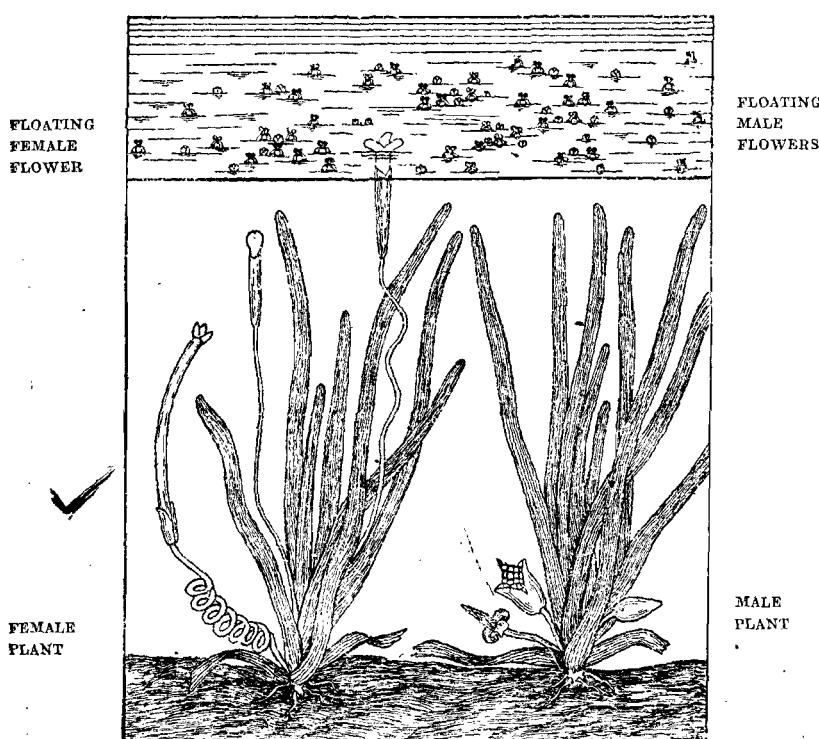

FIG. 204. *Vallisneria*. Left, a female plant with a floating female flower, a submerged flower (-bud) and a fruit (15 cm. long) maturing under water after pollination; right, a male plant with three spadices—young (covered by spathe), mature (with the spathe bursting) and old (after the escape of the male flowers). Male flowers are now seen floating on water.

4. **Zoophily** (*zoon*, animal). Birds, squirrels, bats, snails, etc., also act as useful agents of pollination; for example, birds and squirrels bring about pollination in coral tree and silk cotton tree; bats in *Anthocephalus* (B. & H. KADAM); and snails in certain large varieties of aroids and in snake plant (*Arisaema*—see fig. 138).

Merits and Demerits of Self- and Cross-pollinations. Self-pollination has this merit that it is almost certain in a bisexual flower provided that both stamens and carpels of it have matured at the same time. Continued self-pollination generation after generation has, however, this demerit that it results in weaker progeny. The advantages of cross-pollination are many : (a) it always results in much healthier offspring which are better adapted to the struggle for existence ; (b) more abundant and viable seeds are produced by this method ; (c) new varieties may also be produced by the method of cross-pollination ; and (d) the adaptability of the plants to their environment is better by this method. The disadvantages of cross-pollination are that the plants have to depend on external agencies for the purpose and, this being so, the process is more or less precarious and also less economical as various devices have to be adopted to attract pollinating agents, and that there is always a considerable waste of material (pollen) when wind is the pollinating agent.

Contrivances for Cross-pollination. By cross-pollination better seeds and healthier offspring are normally produced. Nature, therefore, favours this process and helps it by certain contrivances in flowers, which wholly or sometimes partially prevent self-pollination. It must, however, be noted that in many flowers there is still provision for self-pollination if the other method fails.

(1) **Dicliny or Unisexuality.** (a) Unisexual or diclinous flowers, i.e. separate male and female flowers, may be borne by one and the same plant ; such a plant is said to be **monoecious** (*monos*, single ; *oikos*, house), e.g. gourd, cucumber, castor, maize, etc. ; or, (b) these may be borne by two separate plants ; such plants are said to be **dioecious** (*di*, two), e.g. palmyra-palm, papaw, mulberry, etc. In monoecious plants the flowers may be self-pollinated or cross-pollinated, while in dioecious plants cross-pollination is indispensable for the production of seeds.

(2) **Self-sterility.** This is the condition in which the pollen of a flower has no fertilizing effect on the stigma of the same flower. Tea flowers, many grasses, some species of passion-flower, some orchids and mallow are self-sterile. Only pollen applied from another plant of the same or allied species is effective in such cases. Cross-pollination is thus the only method in them for the setting of seeds.

(3) **Dichogamy** (*dicha*, in two). In many bisexual flowers the anther and the stigma often mature at different times. This condition is known as **dichogamy**. Dichogamy often stands as a barrier to self-pollination. There are two conditions of dichogamy: (a) **protogyny** (*protos*, first ; *gyne*, female).

when the gynoecium matures earlier than the anthers of the same flower; here the stigma receives the pollen grains brought from another flower, e.g. *Ficus* (fig. banyan, peepul, etc.), four o'clock plant, *Magnolia*, custard-apple, etc.; and (b) **protandry** (*proto*, first; *andros*, male) when the anthers mature (burst and discharge their pollen) earlier than the stigma of the same flower; here the pollen grains are carried over to the stigma of another flower, e.g. *Clerodendron* (fig. 205), cotton, lady's finger, sunflower, marigold, coriander, rose, etc. Protandry is more common than protogyny.

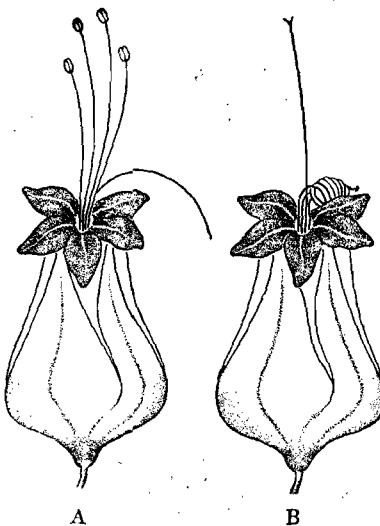

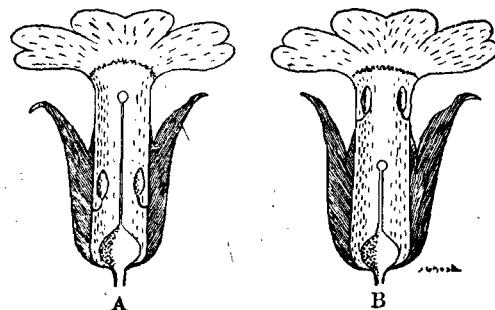

FIG. 205. Protandrous flowers of *Clerodendron*; A, stamens maturing first; B, stigma maturing later.

FIG. 206.
Dimorphic flowers
of primrose.
A, a flower with
long style;
B, a flower with
short style.

(4) **Heterostyly** (*heteros*, different). There are some plants which bear flowers of two different forms. One form bears long stamens and a short style, and the other form bears short stamens and a long style. This is known as *dimorphic heterostyly*. Similarly there may be cases of *trimorphic* heterostyly, that is, stamens and styles of three different lengths borne by three different forms of flowers. In all such cases cross-pollination readily takes place between stamens and styles of the same length borne by different flowers. Dimorphic heterostyly

rity. ~The seed normally bears only one embryo. (2) *Protection of the Embryo.* The seed encloses the embryo and protects it from excessive heat, cold and rain, and also from the attack of insects, birds and other animals. (3) *Storage of Food.* The seed stores up food for the embryo, either in the endosperm or in the cotyledons. This food is utilized by the embryo when the seed germinates. (4) *Seed Dispersal* (see chapter 14). Many seeds have special adaptations by which they are easily dispersed by wind, water and many animals.

CHAPTER 13 *The Fruit*

Development of the Fruit. After fertilization the ovary also begins to grow and gradually it matures into the fruit. The fruit may, therefore, be regarded as a mature or ripened ovary. If, for some reason or other, fertilization fails, the ovary simply withers and falls off. A fruit consists of two portions, viz. the **pericarp** (*peri*, around ; *karpos*, fruit) developed from the wall of the ovary, and the **seeds** developed from the ovules. In some cultivated varieties of oranges, bananas, grapes, apples, pineapples and some other fruits the ovary may grow into the fruit without fertilization. Such a fruit is seedless or with immature seeds and is known as the **parthenocarpic** fruit. The pericarp may be thick or thin ; when thick, it may consist of two or three parts : the outer, called *epicarp*, forms the skin

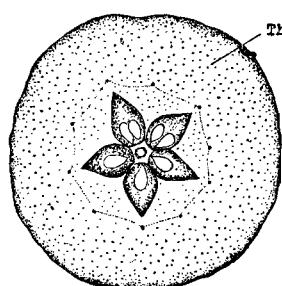

FIG. 209

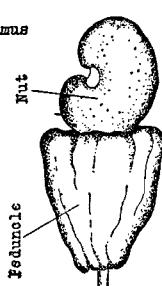

FIG. 210

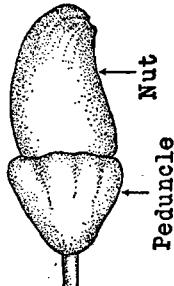

FIG. 211

FIG. 209. Apple in transverse section. FIG. 210. Cashew-nut (*Anacardium*).
FIG. 211. Marking nut (*Semecarpus*).

of the fruit ; the middle, called *mesocarp*, is pulpy in fruits like mango, peach, palms, etc., and the inner, called *endocarp*, is often very thin and membranous, as in orange, or it may be

hard and stony, as in many palms, mango, etc. In many cases, however, the pericarp is not differentiated into these three regions. *Functions of the Fruit.* The fruit gives *protection* to the seed and, therefore, to the embryo. It *stores* food material. It also helps *dispersal* of the seed.

Normally it is only the ovary that grows into the fruit; such a fruit is known as the true fruit. Sometimes, however, other floral parts, particularly the thalamus or even the calyx, may grow and form a part of the fruit; such a fruit is known as the **false fruit**. Common examples of false fruits are apple (fig. 209), pear, cashew-nut (fig. 210), marking nut (fig. 211), rose, *Dillenia* (B. & H. CHALTA), etc.

Dehiscence of Fruits (fig. 212). There are many fruits whose pericarp bursts to liberate the seeds, when the former mature; such fruits are said to be **dehiscent**. There are others again

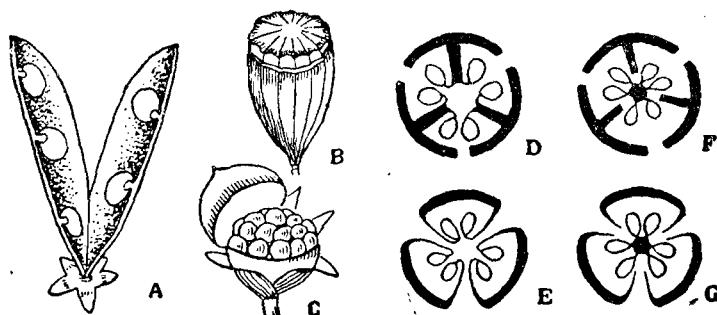

FIG. 212. Dehiscence of fruits. A, sutural (pea); B, porous (poppy); C, transverse (cock's comb); D, loculicidal; E, septicidal; F-G, septifragal.

whose pericarp does not burst, and consequently the seeds cannot be liberated from the fruits until decay of the latter has set in. Fruits that belong to this category are said to be **indehiscent**. Dehiscent fruits open in various ways, as shown in fig. 212, and aid in the dispersal of seeds.

CLASSIFICATION OF FRUITS

All the different kinds of fruits may be broadly classified into three groups, viz. **simple**, **aggregate** and **multiple** or **composite**. A few common types are discussed under each group.

1. **Simple Fruits.** When a single fruit develops from the ovary (either of simple pistil or of syncarpous pistil) of a flower with

or without accessory parts, it is said to be a **simple fruit**. A simple fruit may be dry or fleshy. Dry fruits may again be dehiscent or indehiscent.

1. DEHISCENT OR CAPSULAR FRUITS

(1) **Legume** or **Pod** (fig. 213). This is a dry, one-chambered fruit developing from a simple pistil and dehiscing by both the margins, e.g. pea, bean, pulses, groundnut, etc.

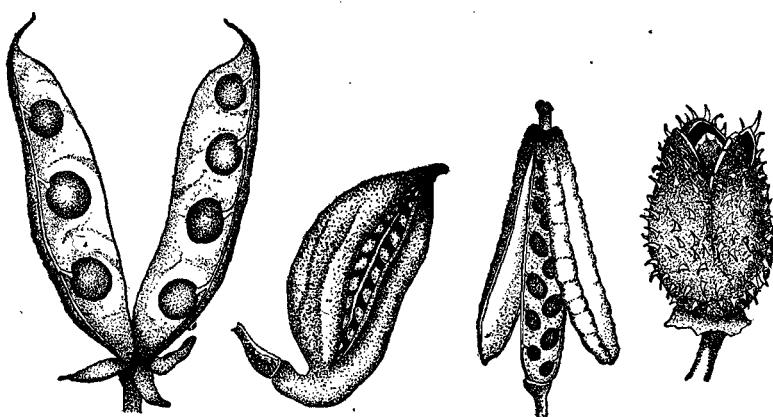

FIG. 213

FIG. 214

FIG. 215

FIG. 216

Fruits. FIG. 213. Legume or pod of pea. FIG. 214. Follicle of madar (*Calotropis*). FIG. 215. Siliqua of mustard. FIG. 216. Capsule of *Datura*.

(2) **Follicle** (fig. 214). This is also a dry, one-chambered fruit like the previous one, but it dehisces by one suture only, e.g. madar, blood flower, periwinkle, larkspur, etc. Follicles commonly develop in an aggregate of two to many fruits.

(3) **Siliqua** (fig. 215). This is a dry, long, narrow, two-chambered fruit developing from a *bicarpellary* pistil with two parietal placentae. It dehisces from below upwards by both the margins. The ovary is one-chambered at first, but soon it becomes two-chambered owing to the development of a false partition wall, called *replum*, which extends from one placenta to the other, e.g. mustard, radish, etc.

(4) **Capsule** (figs. 216-17). This is a dry, one- to many-chambered fruit developing from a syncarpous pistil, and dehiscing in various ways. All dehiscent fruits developing from a syncarpous pistil are commonly known as capsules, e.g. cotton, lady's finger, *Datura*, cock's comb, poppy, etc.

II. INDEHISCENT OR ACHEINAL FRUITS

(1) **Achene** (fig. 218). An achene is a small, dry, one-seeded fruit developing from a single carpel; but unlike the next one, the pericarp of this fruit is free from the seed-coat, e.g.

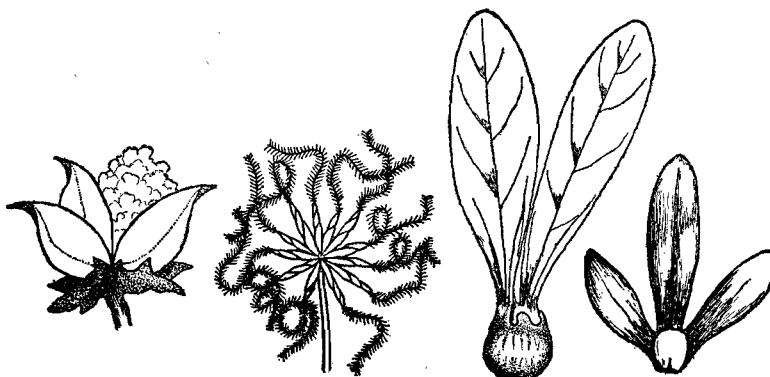

FIG. 217

FIG. 218

FIG. 219

FIG. 220

Fruits (contd.). FIG. 217. Capsule of cotton. FIG. 218. Achenes of *Naravelia*. FIG. 219. Samara of *Dipterocarpus*. FIG. 220. Samara of *Hiptage*.

rose, buckwheat, *Naravelia* (fig. 218), *Clematis* (see fig. 237A), etc. Achenes commonly develop in an aggregate.

(2) **Caryopsis** (see figs. 25-6). This is a very small, dry, one-seeded fruit developing from a simple pistil, with the pericarp fused with the seed-coat, e.g. rice, wheat, maize, bamboo, grass, etc.

(2) **Cypsela** (see fig. 236A). This is a dry, one-seeded fruit developing from an inferior bicarpellary ovary, e.g. sunflower, marigold, *Cosmos*, etc.

(4) **Nut**. This is a dry, one-seeded fruit developing from a superior syncarpous pistil, with the pericarp hard and woody, e.g. cashew-nut, chestnut, oak, etc.

(5) **Samara** (figs. 219-20). This is a dry, one or two-seeded fruit with one or more thin flat membranous wings, e.g. *Hiptage* (B. MADHABI-LATA), wood-oil tree (*Dipterocarpus*; B. GARJAN), *Hopea*, *Shorea* (B. & H. SAL), etc.

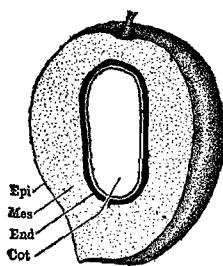

(6) **Schizocarp**. This is a dry fruit partitioned between the seeds into a number of compartments, and splits through the partitions separating the compartments. It does not, however, dehisce to liberate the seeds, e.g. sensitive plant, nicker bean (*Entada*; B. GILA), coriander, carrot, castor, etc.

III. FLESHY FRUITS

(1) **Drupe** (fig. 221). This is a fleshy, one- or more-seeded fruit with the pericarp differentiated into the outer skin or epicarp, often fleshy or sometimes fibrous mesocarp, and *hard and stony* endocarp, and hence this fruit is also known as **stone-fruit**, e.g. mango, plum, coconut-palm, palmyra-palm, country almond, etc.

(2) **Becca** or **Berry** (fig. 222). This is a fleshy, usually many-seeded fruit, e.g. tomato, gooseberry, grapes, banana, guava, papaw, etc. With the growth of the fruit the seeds separate

FIG. 221

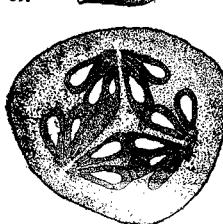

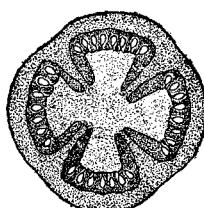

FIG. 223

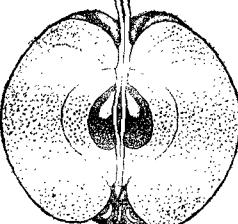

FIG. 224

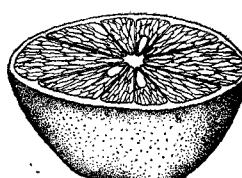

FIG. 225

Fruits (*contd.*). FIG. 221. Drupe of mango; *Epi*, epicarp; *Mes*, mesocarp; *End*, endocarp; *Cot*, cotyledon. FIG. 222. Berry of tomato; *A*, in longitudinal section; *B*, in transverse section. FIG. 223. Pepo of cucumber in transverse section. FIG. 224. Pome of apple (see also FIG. 209). FIG. 225. Hesperidium of orange.

from the placentae and lie free in the pulp. It is not infrequent to find one-seeded berry, e.g. date-palm, *Artabotrys*, (B. & H. KANTALI-CHAMPA), etc.

(3) **Pepo** (fig. 223). This is also a fleshy, many-seeded fruit like the berry but it develops from an inferior, one-celled or spuriously three-celled, *syncarpous* pistil with parietal placentation, e.g. gourd, cucumber, melon, water melon, squash, etc. In pepo the seeds, lying embedded in the pulp, remain attached to the placentae.

(4) **Pome** (fig. 224). This is an inferior, two- or more-celled, fleshy, *syncarpous* fruit surrounded by the thalamus. The fleshy edible part is composed of the thalamus, while the actual fruit lies within, e.g. apple and pear.

(5) **Hesperidium** (fig. 225). This is a superior, many-celled, fleshy fruit with axile placentation. Here the endocarp projects inwards forming distinct chambers, and the epicarp and the mesocarp, fused together, form the separable skin or rind of the fruit, e.g. orange, shaddock, lemon etc.

2. **Aggregate Fruits.** An aggregate fruit is a collection of simple fruits (or fruitlets) developing from an apocarpous pistil (free carpels) of a flower. Since each free carpel develops into a fruit there will be as many fruits as there are free carpels in a flower. An aggregate of simple fruits borne by a single flower is otherwise known as an 'etaerio', and the common forms of etaerios are: (1) *an etaerio of follicles*, e.g. *Michelia*, madar, periwinkle, larkspur, etc.; (2) *an etaerio of achenes*, e.g. rose, lotus, strawberry, *Naravelia*, etc.; (3) *an etaerio of drupes*, e.g. raspberry; and (4) *an etaerio of berries*, e.g. custard-apple, *Artabotrys* (B. & H. KANTALI-CHAMPA), mast tree (*Polyalthia*; B. DEBDARU; H. DEVADARU or ASHOK), etc.

3. **Multiple or Composite Fruits.** A multiple or composite fruit is that which develops from an inflorescence where the flowers are crowded together and often fused with one another.

(1) **Sorosis** (see fig. 365). This is a multiple fruit developing from a spike or spadix. The flowers fuse together by their succulent sepals and at the same time the axis bearing them grows and becomes fleshy or woody, and as a result the whole inflorescence forms a compact mass, e.g. pineapple, screwpine and jack-fruit. Mulberry (see fig. 142) is also a sorosis, but here the fleshy part is made of loosely attached sepals.

(2) **Syconus** (see fig. 153). The syconus develops from a hollow, pear-shaped, fleshy receptacle which encloses a number of minute, male and female flowers. The receptacle grows, becomes fleshy and forms the so-called fruit. It really encloses a number of true fruits or achenes which develop from the female flowers lying within the receptacle, e.g., fig, banyan, peepul, etc.

Some Common Fruits and their Edible Parts

Apple (pome)—fleshy thalamus. **Banana** (berry)—mesocarp and endocarp. **Cashew-nut** (nut)—peduncle and cotyledons. **Coconut-palm** (fibrous drupe)—

endosperm. **Cucumber** (*pepo*)—mesocarp, endocarp and placentae. **Custard-apple** (*etaerio* of berries)—fleshy pericarp of individual berries. **Date-palm** (1-seeded berry)—pericarp. **Dillenia** (special)—accrescent calyx. **Fig** (*sycanus*)—fleshy receptacle. **Jack** (sorosis)—bracts, perianth and seeds. **Grape** (berry)—pericarp and placentae. **Guava** (berry)—thalamus and pericarp. **Indian plum** (drupe)—mesocarp including epicarp. **Litchi** (1-seeded nut)—fleshy aril. **Maize, oat, rice and wheat** (*caryopsis*)—starchy endosperm. **Mango** (drupe)—mesocarp. **Melon** (*pepo*)—mesocarp. **Orange** (*hespiridium*)—juicy placental hairs. **Palmyra-palm** (fibrous drupe)—mesocarp. **Papaw** (berry)—mesocarp. **Pea** (legume)—cotyledons. **Pear** (pome)—fleshy thalamus. **Pineapple** (sorosis)—outer portion of receptacle, bracts and perianth. **Pomegranate** (special)—juicy outer coat of the seed. **Pummelo or shaddock** (*hespiridium*)—juicy placental hairs. **Strawberry** (*etaerio* of achenes)—succulent thalamus. **Tomato** (berry)—pericarp and placentae. **Wood-apple** (special)—mesocarp, endocarp and placentae.

CHAPTER 14 *Dispersal of Seeds and Fruits*

If seeds and fruits fall directly underneath the mother plant and the seedlings grow up close together they soon exhaust the soil of its essential food constituents. Besides, the available space, light and air under such a condition fall far short of the demand. A struggle for existence thus ensues, the consequence of which may be fatal to all of them. To guard against this the seeds and fruits have developed various devices for their wide distribution so that some of them at least may meet with favourable conditions of germination and normal growth. Thus the risk of a species of plants becoming extinct is practically averted.

i. Seeds and Fruits dispersed by Wind. Seeds and fruits have various adaptations like wings, pappus, hairs, etc., which help them to be carried away by the wind to a shorter or longer distance from the parent plant.

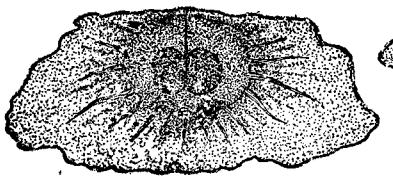

FIG. 226
Winged Seeds. FIG. 226. *Oroxylon*. FIG. 227. *Cinchona*. FIG. 228. Crepe tree.

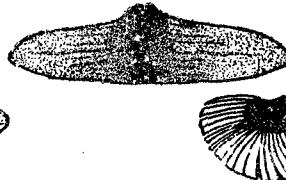

FIG. 227

FIG. 228

Crepe tree.

FIG. 228

Crepe tree.

(1) **Wings.** Seeds and fruits of many plants develop one or more thin membranous wings for facility of dispersal by the

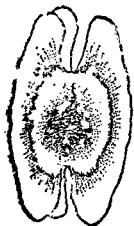

FIG. 229

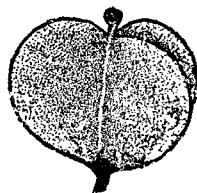

FIG. 230

FIG. 229. Winged seed of drumstick (*Moringa*). FIG. 230 Winged fruit of yam (*Dioscorea*).

B. GARJAN—fig. 231), *Hiptage* (B. MADHABI-LATA, H. MADHU-LATA—fig. 232) and *Shorea* (B. & H. SAL—fig. 233).

(2) **Parachute Mechanism.** In many plants of the sunflower family the calyx is modified into hair-like structures known

wind. Thus seeds of *Oroxylon* (B. SONA; H. ARLU—fig. 226), *Cinchona* (fig. 227), crepe tree (B. & H. JARUL—fig. 228), drumstick (B. SAJINA; H. SAINJNA—fig. 229), etc., are provided with wings for this purpose. Similarly many fruits are also provided with one or more wings to achieve the same end, e.g. yam (*Dioscorea*; fig. 230), wood-oil tree (*Dipterocarpus*;

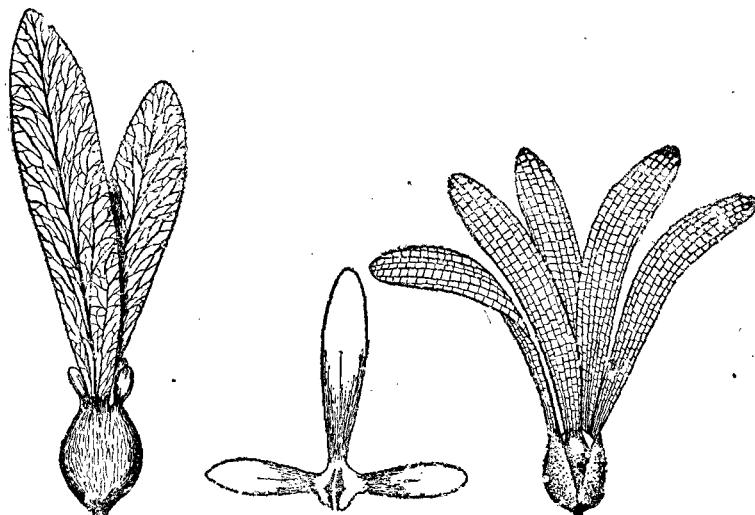

FIG. 231

Winged Fruits. FIG. 231. *Dipterocarpus*. FIG. 232. *Hiptage*.
FIG. 233. *Shorea*.

as **pappus** (fig. 236 A). This pappus is persistent in the fruit, and opens out in an umbrella-like fashion. Thus acting like a parachute it helps the fruit to be carried by air current to a distance.

(3) **Censer Mechanism.** In some plants, as in poppy, prickly poppy, bath sponge, cock's comb, pelican flower (*Aristolochia*

gigas; B. *HANSA-LATA*—figs. 234-5), etc., the fruit dehisces, and when it is disturbed by the wind, the seeds are thrown out.

FIG. 234

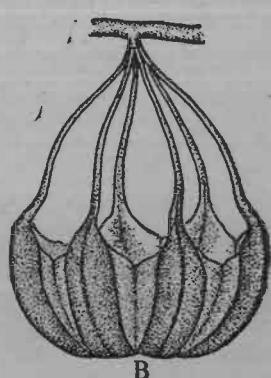

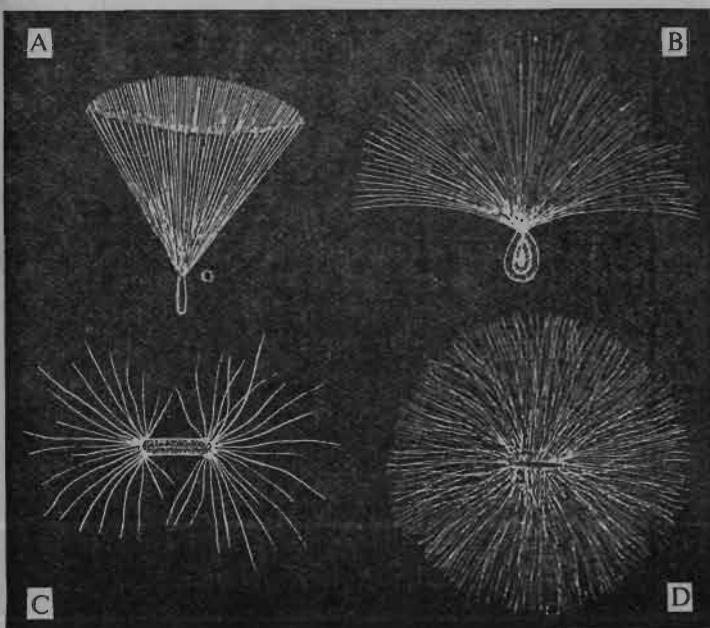

FIG. 235

FIG. 234. Pelican flower (*Aristolochia*) with duck-shaped flowers.

FIG. 235. A fruit of the same like a hanging basket.

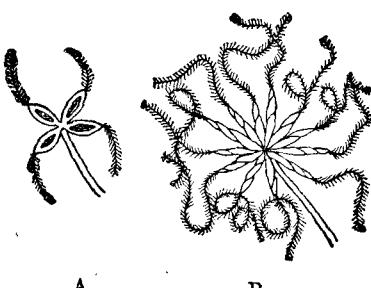

Hairy Fruit and Seeds. FIG. 236. A, pappus of a Compositae fruit; B, madar (*Calotropis*); C, devil tree (*Alstonia*); D, cotton.

(4) **Hairs.** A tuft of hairs or a dense coating of hairs on seeds and fruits is very useful for their distribution by the wind, e.g. madar (fig. 236 b), devil tree (fig. 236 c), cotton (fig. 236 d) etc.

(5) **Persistent Styles.** In virgin's bower (*Clematis*; H. BELKUN—fig. 237 A) and traveller's joy (*Naravelia*; B. CHHAGALBATI—fig. 237 B) the styles are persistent and very feathery. The fruits are thus easily carried away by the wind.

(6) **Light Seeds and Fruits.** Some seeds and fruits are so

Persistent styles. FIG. 237. A, fruits of *Clematis*; B, fruits of *Naravelia*.

light and minute in size that they may easily be carried away by the gentlest breeze. Thus orchids often bear millions of dust-like seeds (smallest in the vegetable kingdom) in a single fruit (capsule). Seeds of *Cinchona* (the quinine-yielding plant) are also very small, flat, extremely light, and provided with a membranous wing (see fig. 227). There are about 2,470 seeds per gramme.

2. Seeds and Fruits dispersed by Water. Seeds and fruits to be dispersed by water usually develop floating devices in the form of spongy or fibrous outer coats. The fibrous fruit of coconut is capable of floating long distances in the sea without suffering any injury. Hence coconut forms a characteristic vegetation of sea-coasts and marine islands. The fruit of double coconut (*Lodoicea*; fig. 238), a native of Seychelles, which bears the largest seed in the vegetable kingdom, is also distributed likewise by ocean currents. The top-shaped spongy thalamus of lotus (see fig. 158 c) bearing the fruits on its surface floats on water and is drifted by water-current or by wind. Seeds of water lily are small and light, and are further provided with an *aril* which encloses air.

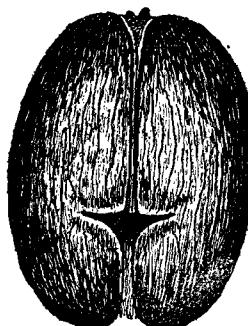

FIG. 238. Double coconut seed (*Lodoicea*).

3. **Seeds dispersed by Explosive Fruits.** Many fruits burst with a sudden jerk, with the result that seeds are scattered on all sides. Common examples of explosive fruits are balsam, wood-

FIG. 239. *Ruellia*; note the explosive fruit.
sorrel, night jasmine, castor, etc. Ripe fruits of balsam burst suddenly. The valves roll up inwards, and the seeds are ejected

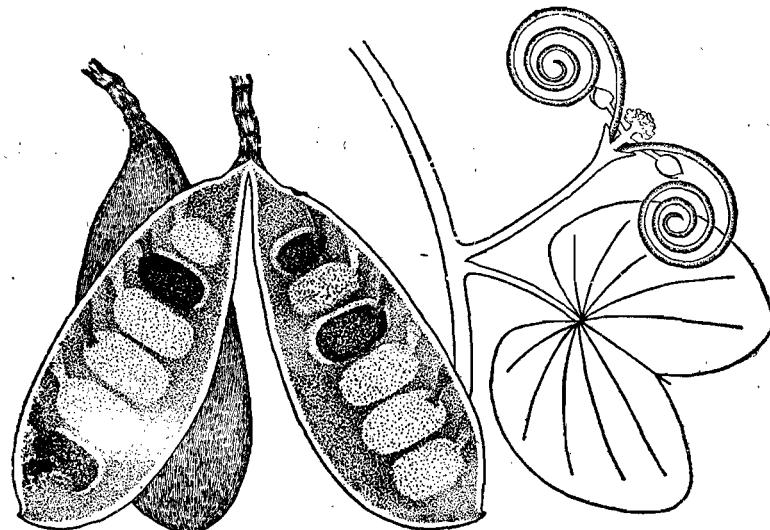

FIG. 240. *Bauhinia vahlii*; note the explosive fruit.
with great force and scattered in all directions. Dry fruits of
Ruellia (fig. 239) coming in contact with water, particularly

after a shower of rain, burst suddenly with a noise and scatter the seeds. Further the seed is provided with a curved hook (jaculator) which straightens out instantly and jerks out the seed. Mature fruits of *Phlox*, *Andrographis* (B. KALMEGH ; H. MAHATITA), *Barleria* (B. JHANTI ; H. VAJRADANTI), etc., burst suddenly when the air is dry, particularly at mid-day.

A very interesting example of bursting fruits is found in camel's foot climber (*Bauhinia vahlii*; B. LATIA-KANCHAN; H. CHAMBULI). Its long pods, sometimes as long as 30 cm., explode with a loud noise like a cracker, scattering the seeds in all directions (fig. 240).

4. Seeds and Fruits dispersed by Animals. Many seeds and fruits are provided with hooks, barbs, spines, stiff hairs and

sticky glands on their surface, by means of which they stick to the body of woolly animals as well as to the clothing of mankind, and are often carried by them to distant places. Thus it is seen that the fruits of *Xanthium* (B. & H. OKRA—fig. 241) and *Urena* (B. BAN-OKRA ; H. BACHATA—fig. 242)

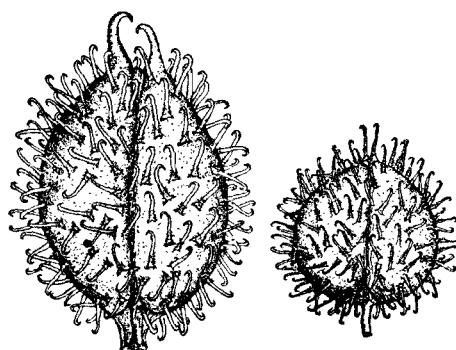

FIG. 241. Fruit of *Xanthium* with curved hooks. FIG. 242. Fruit of *Urena* with curved hooks.

FIG. 243. Fruit of *Boerhaavia* with sticky glands (see also FIG. 294B). FIG. 244. Flowers of *Pupalia* with hooked bristles. FIG. 245. Fruit of tiger's nail (*Martynia*) with a pair of sharp, curved hooks.

FIG. 245

are covered with numerous curved hooks. Seeds (fruits) of spear grass and love-thorn (B. CHORKANTA) have a cluster of stiff hairs pointing upwards. Fruits of *Eoerhaavia* (B. PUNARNAVA; H. THIKRI—fig. 243) are provided with sticky glands. In *Pupalia* (fig. 244) the perianth bears clusters of hooked bristles. Tiger's nail (*Martynia*; B. BAGH-NAKHI—fig. 245) is a very interesting case. Its seed is provided with two very sharp-pointed, stiff and bent hooks by which it easily sticks to the body of woolly animals.

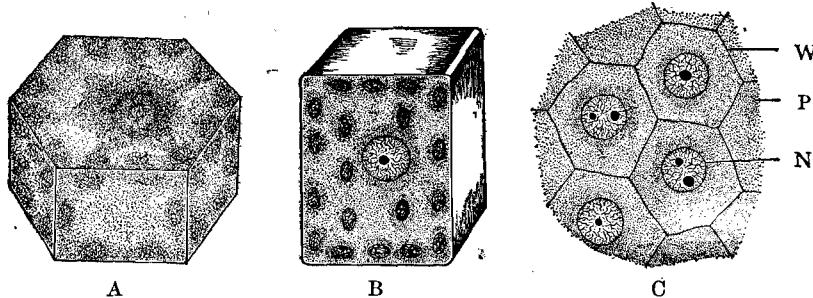

Human beings, birds, squirrels, bats and jackals are also useful agents in distributing seeds and fruits over wide areas.

PART II HISTOLOGY

CHAPTER I *The Cell*

An Early History. The study of histology dates from the year 1665, when plant cells were discovered for the first time. It was Robert Hooke, an Englishman, who first studied the internal structure of a thin slice of bottle cork with the help of a microscope improved by himself. He discovered for the first time a honey-comb-like structure in it, and to each individual cavity of such a structure he applied the term **cell**. It was then only the cell-wall that was noticed, this being the prominent part of the cell. Other prominent workers of that time, who studied plant tissues under the microscope, were Leeuwenhoek, Grew and Malpighi. Leeuwenhoek of Delft in Holland was the first to invent microscope. He was a dry-goods dealer but at the age of 21 in the year 1653 he developed a mania for grinding lenses. He pursued this work with zeal and assiduity and within 20 years (1653-1673) accomplished marvellous fineness, accuracy and perfection in his lenses. He gave a demonstration of his microscope before the Royal Society in 1667. He was the first to discover bacteria, protozoa and other minute forms of life—'the wretched beasties', as he called them, under his own microscope. Grew, an English physician and botanist, published his first paper on plant tissues in 1671. Malpighi, an Italian physician, studied the various tissues of vascular plants, and published his first paper in 1675. In 1838-39 Schleiden, a German botanist, and Schwann, a German zoologist, proved definitely that both plants and animals are cellular in character, and founded the **cell theory**.

Cell-structure. We have already learnt (see Introduction) that the plant body is composed of cells which are its fundamental structural and functional units. A plant cell may be defined

Plant Cells. FIG. 246. A, polygonal cell (three-dimensional diagram); B, a cubical cell in section (three-dimensional diagram); C, a group of cells in section. W, cell-wall; P, protoplasm; N, nucleus.

as a unit or independent, tiny or microscopic mass of **protoplasm** enclosing in it a denser spherical or oval body, called

the **nucleus**, and bounded by a distinct wall, called the **cell-wall**. Protoplasm and nucleus are living, while the cell-wall is non-living; the latter has been formed by the protoplasm to maintain its shape and firmness and to afford necessary protection. Cells vary widely in shapes and sizes. In shapes they may commonly be spherical, oval, polygonal, cubical or narrow and elongated. When young, they are often spherical or of like nature. Usually they are very minute in size invisible to the naked eye. The average size of fully developed rounded or polygonal cells varies between $1/10$ th and $1/100$ th of a millimetre. There are, however, many cells far beyond these limits.

LIVING CELL-CONTENTS (THE PROTOPLAST)

Protoplasm (see also Introduction) is the only substance that is endowed with life; plants and animals containing this substance in their body are, therefore, regarded as living. The protoplasm has to perform the manifold vital functions of a cell such as manufacture of food, nutrition, growth, respiration, reproduction, etc., and as such for the sake of convenience and efficiency of work it becomes differentiated into distinct living (protoplasmic) bodies, viz. (1) **cytoplasm**, (2) **nucleus** and in special cells (3) **plastids**, of which the first two are constant in all living cells. Such differentiated protoplasmic bodies have certain specialized functions. It must distinctly be noted that these living bodies are never formed afresh in the cells but always develop from pre-existing ones by divisions and that one kind of living body cannot give rise to another kind.

DIFFERENTIATED PARTS OF PROTOPLASM

1. **Cytoplasm.** The protoplasmic mass of a cell leaving out the nucleus and the plastids is otherwise called cell-protoplasm or **cytoplasm**. When the cell is young the cytoplasm completely fills its cavity, i.e. the space between the cell-wall and the nucleus (fig. 247 A), but as the cell rapidly increases in size it cannot keep pace with the growth of the cell-wall. Consequently a number of small (non-protoplasmic) cavities appear in it; these are called **vacuoles** (*vacuus*, empty; fig. 247 B). With further growth of the cell all these small vacuoles fuse together into a large one which then occupies by far the greater part of the cell, pushing the cytoplasm outwards as a thin-lining layer against the cell-wall (fig. 247 C). In some cells com-

paratively small vacuoles persist and then the cytoplasm forms delicate strands around them (fig. 247 D). The vacuole is filled with a fluid called the **cell-sap** which is water containing certain mineral salts and food substances dissolved in it. The vacuole is thus a tiny reservoir of the cell from which the cytoplasm draws water and other materials according to its

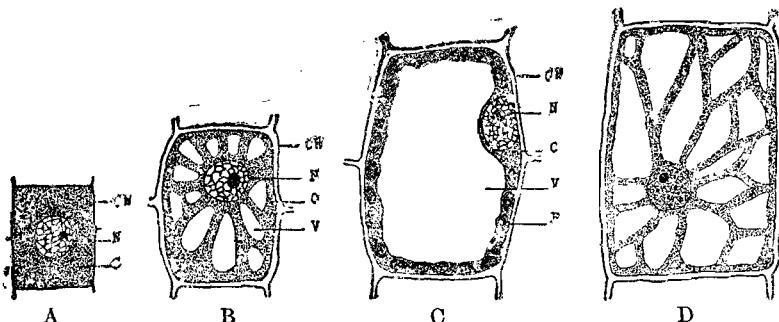

FIG. 247. A-C, growth of a cell and development of vacuoles; D, a cell with many vacuoles; CW, cell-wall; N, nucleus; C, cytoplasm; V, vacuole; and P, plastid.

need. Referring to the cytoplasm again we find that it has three distinct parts: (1) its outer surface forms an extremely thin and delicate membrane called the **ectoplasm**; (2) its middle part is granular and is called the **endoplasm**; and (3) its innermost part surrounding the vacuole as a thin membrane is called the **vacuole membrane** or **tonoplasm**. The ectoplasm controls the entrance and exit of water and many chemical substances into and out of the cell, the tonoplasm does the same in respect of the vacuole, while the endoplasm performs the general functions of the cytoplasm.

Tests. (a) **Iodine** solution stains protoplasm **brownish yellow**. (b) Dilute **caustic potash** dissolves it. (c) **Millon's reagent** (nitrate of mercury) stains it **brick-red**; the reaction is hastened by heating.

Movements of Protoplasm. Protoplasm shows movements of different kinds. Naked masses of cytoplasm, not enclosed by the cell-wall, show two kinds of movement—**ciliary** and **ameoboid**. The cytoplasm, enclosed by the cell-wall, shows a streaming movement within it, which is spoken of as **cyclosis**. Cyclosis is of two kinds—**rotation** and **circulation**.

(1) **Ciliary movement** (fig. 248) is the *swimming* movement of free, minute, protoplasmic bodies provided with one or more tail-like structures, called **cilia**. By the vibration of these

cilia such ciliary bodies move or swim freely and rapidly in water, e.g. zoospores of many algae and fungi, male gametes of mosses and ferns, etc.

(2) **Amoeboïd movement** (fig. 249) is the *creeping* movement of naked masses of protoplasm (i.e. not enclosed by cell-wall). They move or creep by the protrusion of one or more parts

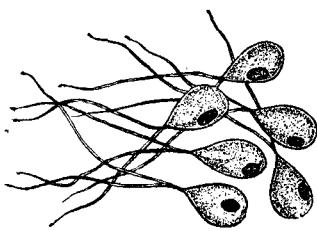

FIG. 248

Movements of Protoplasm. FIG. 248. Ciliary movement. FIG. 249. Amoeboïd movement.

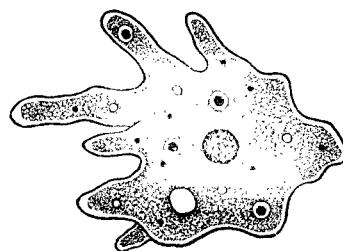

FIG. 249

of their body in the form of false feet or pseudopodia (*pseudos*, 'false'; *podos*, 'foot') and withdrawing the same at the next moment, e.g. some slime fungi, certain zoospores, etc.

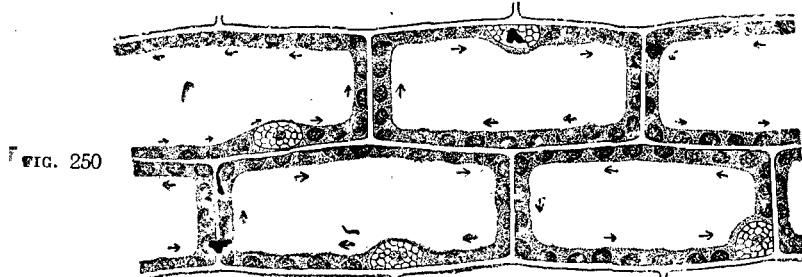

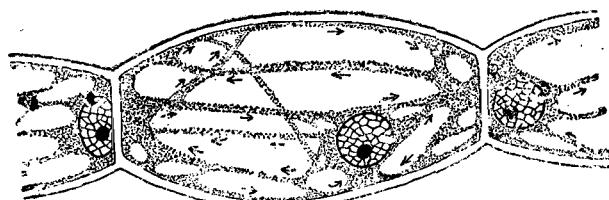

FIG. 250

FIG. 251

Movements of Protoplasm (contd.). FIG. 250. Rotation in the leaf of *Vallisneria*. FIG. 251. Circulation in the staminal hair of *Commelina obliqua*.

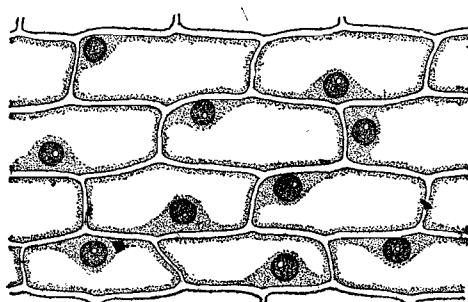

(3) **Rotation** (fig. 250). When the protoplasm moves or streams within a cell alongside the cell-wall, clockwise or anti-

clockwise, round a large central vacuole, the movement is called rotation. The direction of movement is constant so far as a particular cell is concerned. As the protoplasm rotates, it carries in its current the nucleus and the plastids. Rotation is distinctly seen in *Vallisneria*, *Hydrilla*, *Chara* and also in many other aquatic plants.

(4) **Circulation** (fig. 251). When the protoplasm moves or *streams* in different directions within a cell in the form of delicate strands round a number of small vacuoles, the movement is called circulation. Circulation is very distinctly seen in the staminal hairs of *Commelina obliqua*, spiderwort (*Tradescantia*), in the young shoot-hairs of gourd and in many other land plants.

2. **Nucleus.** The nucleus is a specialized protoplasmic body, much denser than the cytoplasm, and is commonly spherical or oval. It always lies embedded in the cytoplasm. The nucleus is universally present in all living cells. In the higher plants there is almost always a single nucleus in each cell, while in many algae and fungi numerous nuclei may be present. In lower organisms like bacteria and blue-green algae true nuclei are absent, but there is a corresponding nuclear material. Nuclei may vary widely in sizes. Their usual size is between 5 and 25 microns (or $1/200$ and $1/40$ mm.). A nucleus can never be newly formed, but it multiplies in number by division of the pre-existing one.

FIG. 252.
Cellular structure
and nuclei in
onion scale.

Structure. Each nucleus (fig. 253) is surrounded by a thin, transparent membrane known as (1) the **nuclear membrane** which separates the nucleus from the surrounding cytoplasm. Within the membrane, completely filling up the space, there is a dense but clear mass of protoplasm known as (2) the **nuclear sap** or **nucleoplasm**. Suspended in the nucleoplasm

there are numerous fine crooked threads, loosely connected here and there, forming a sort of network, called (3) the **nuclear reticulum** or **chromatin network**. The threads are made of a substance known as chromatin or nuclein which is strongly stainable. The chromatin or nuclein is a nucleoprotein which is a phosphorus-containing protein (see below). One or more highly refractive, very minute and usually spherical bodies may be seen in the nucleoplasm; these are known as (4) the nucleoli (sing. nucleolus).

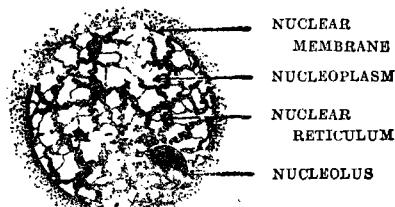

FIG. 253. Nuclear structure.

Chemical Composition. The chemical composition of the nucleus is very complex, mainly consisting of a variety of proteins (see p. 143). A special kind of protein called *nuclein* is constant in the nucleus, occurring in the reticulum only but not in other parts. Nuclein is a phosphorus-containing protein (or nucleoprotein) made of carbon, hydrogen, oxygen, nitrogen, sulphur and phosphorus.

Functions. The nucleus and the protoplasm are together responsible for the life of a cell and the various vital functions performed by it. If they are separated both of them die. The nucleus, however, is regarded as the controlling centre of all vital activities of the cell, particularly assimilation of food and respiration. The specific functions performed by the nucleus are as follows:

(1) The nucleus takes a direct part in reproduction. Two reproductive nuclei called gametes (egg-cell and male gamete) fuse together to give rise to an oospore which grows into an embryo. Thus nuclei are directly concerned in the process of reproduction.

(2) The nucleus takes the initiative in cell division, i.e. it is the nucleus that divides first and this is followed by the division of the cell. This is how the cells multiply in number and the plant body grows.

(3) The nucleus is regarded as the *bearer* of hereditary characters, i.e. it is through the media of two reproductive nuclei that the characteristics of parent plants are transmitted to the offspring.

3. **Plastids.** Besides the nucleus, the cytoplasm of certain cells which have to perform specialized functions encloses many small specialized protoplasmic bodies, usually discoidal, spherical or oval in shape ; these are called **plastids** (see fig. 250). They are present in all plants except bacteria, fungi and blue-green algae. Plastids are living. They are never formed afresh, but multiply in number by division of the pre-existing ones. According to their colour the plastids are of three types, viz. **leucoplasts**, **chloroplasts** and **chromoplasts**. One form of plastids can change into another ; as for example, leucoplasts change into chloroplasts when the former are exposed to light for a prolonged period ; similarly, chloroplasts change into leucoplasts in the continued absence of light ; similar changes may take place in chromoplasts. In the young tomato fruit the leucoplasts gradually change into chloroplasts which finally turn into chromoplasts as the fruit ripens.

(1) **Leucoplasts** (*leucos*, white). These are colourless plastids. Leucoplasts occur most commonly in the storage cells of roots and underground stems ; they are also found in other parts not exposed to light. Their function is to convert sugar into starch, an insoluble food substance, for the purpose of storage.

(2) **Chloroplasts** (*chloros*, green). These are green plastids, their colour being due to the presence of a green *pigment* (colouring matter), called **chlorophyll** ; sometimes the green colour may be masked by other colours. Chloroplasts are only found in parts exposed to light and occur abundantly in green leaves. They absorb carbon dioxide from the air and energy from the sunlight ; utilize this energy in manufacturing sugar and starch from this carbon dioxide and the water absorbed from the soil ; and liberate oxygen (by splitting the water) which escapes to the surrounding air.

Chlorophyll is not one simple substance, but a mixture of four different pigments, viz. chlorophyll *a* (blue-black), chlorophyll *b* (green-black), carotene (orange-red) and xanthophyll (yellow). Chlorophyll *a* and chlorophyll *b* are associated with each other in the chloroplast, but carotene and xanthophyll may also occur without chloroplast in any part of the plant. In old brown leaves chlorophyll becomes decomposed, while carotene and xanthophyll are left behind. Chlorophyll is not soluble in water. It forms about 8% of the dry weight of the chloroplast, while carotene and xanthophyll form about 2%.

Functions. It is definitely known that chlorophyll absorbs

energy from the sunlight. It may also help in the chemical process involved in the manufacture of food by the chloroplasts.

Extraction of Chlorophyll. Chlorophyll as a whole can be easily extracted from the leaf by boiling it for a minute or so and then dipping it into methylated spirit for some time. When all the chlorophyll is extracted the leaf becomes colourless. The chlorophyll solution examined through transmitted light appears deep green in colour, but by reflected light it appears blood-red in colour. This is the physical property of chlorophyll, called *fluorescence*. Then to the chlorophyll extract a small quantity of benzene is added and the whole solution briskly shaken. It is then allowed to settle for a few minutes. Benzene floats on the top (green solution) carrying chlorophyll, while alcohol settles at the bottom (yellow solution) retaining carotene and xanthophyll.

Chemical composition of chlorophyll

Chlorophyll <i>a</i>	$-C_{55}H_{72}O_5N_4Mg$	Carotene	$-C_{40}H_{56}$
Chlorophyll <i>b</i>	$-C_{55}H_{70}O_6N_4Mg$	Xanthophyll	$-C_{40}H_{58}O_2$

(3) **Chromoplasts** (*chroma*, colour). These are variously coloured plastids—yellow, orange and red. They are mostly present in the petals of flowers and in fruits, and the colouring matters (pigments) associated with them are **xanthophyll** (yellow) and **carotene** (orange-red) which occur in different proportions. Chromoplasts occurring in the petals of flowers make them showy and attractive to invite insects for the purpose of pollination. (Most other colours of flowers such as violet, purple, blue, brown and often red are due to the presence of a group of colouring matters known as **anthocyanins** which remain dissolved in the cell-sap.)

PARTS OF A CELL

—	cytoplasm—ectoplasm, endoplasm and tonoplasm
living	nucleus—nuclear membrane, nucleoplasm, nuclear reticulum and nucleoli
—	plastids—leucoplasts, chloroplasts and chromoplasts
—	cell-wall (made of cellulose)
non-living	vacuole (filled with cell-sap)

THE CELL-WALL

Formation of the Cell-wall. Life begins as a single naked cell, that is, as a small mass of protoplasm with a prominent nucleus but no cell-wall. Protoplasm being a very soft and

delicate substance, its first need is self-protection. For this purpose, before it grows any further in size or undergoes division, it forms a wall round itself. The wall is the secretion product of the protoplasm, that is, to form it the protoplasm begins to secrete minute granules on the outer surface of its body. As more granules are secreted they fuse together, resulting in a complete but very thin and delicate wall, i.e. the **cell-wall**, and the protoplasm becomes covered by it. The cell-wall forms a framework round the protoplasm, maintains its form and protects it from external injury. Besides, cell-walls form the skeleton of the plant body, and are responsible for its strength and rigidity.

Growth of the Cell-wall. The cell-wall, when formed first, is a very thin and delicate layer. But as the cell grows the wall undergoes both chemical and physical changes. Physical changes are: growth of the wall in surface area and growth of it in thickness. (1) Growth of the cell-wall in surface area, i.e. its increase in size, takes place in the early stage of the cell and is due to stretching of the cell-wall in one or more directions accompanied by an addition, within the original wall, of new solid particles secreted

by the protoplasm. (2) Growth of the cell-wall in thickness, on the other hand, is mainly due to deposition of definite thin plates or layers by the protoplasm, one after another, on the inner surface of the original wall. When the cell-wall becomes considerably thickened, it shows a *stratified* appearance, that is, the appearance of a number of strata or layers arranged in a series. The original cell-wall between two contiguous cells can still be recognized under the microscope. This

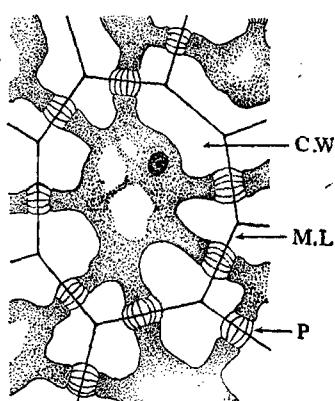

FIG. 254. Cells of the endosperm of date seed. C.W., cell-wall (reserve cellulose); M.L., middle lamella; P, protoplasmic threads.

original or middle wall is known as the **middle lamella** (fig. 254). It is composed of calcium pectate. It is further seen

that the protoplasm of one cell is connected with that of the neighbouring one by fine *protoplasmic threads* or strands passing through extremely minute pits (not visible under the microscope) that develop in the cell-wall.

Secondary Thickening of the Cell-wall. The secondary thickening of the cell-wall takes place in vessels (see fig. 289) and tracheids (see figs. 287-88); after they have grown considerably and attained their full dimension their walls begin to thicken. The thickening in these cases is due to the deposit of a hard substance, called lignin, on the inner surface of the cell-wall. This deposit of lignin takes the following patterns. All lignified elements are dead.

(1) **Annular** or **ring-like** (fig. 255), when the deposit of lignin is in the form of rings. (2) **Spiral** (fig. 256), when the thickening takes the form of a spiral band. (3) **Scalariform**

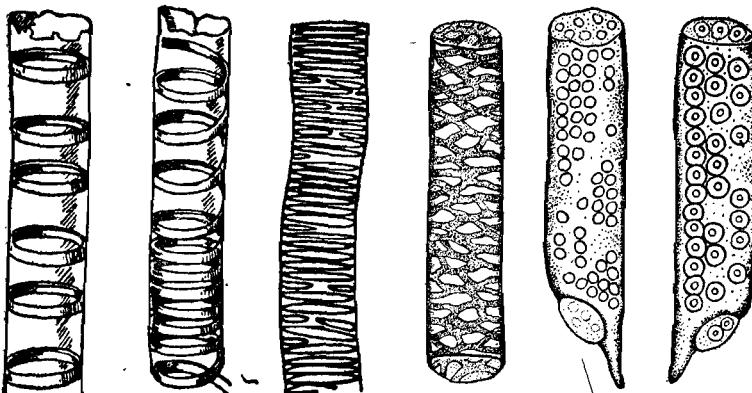

FIG. 255

(with simple pits). FIG. 260. Pitted (with bordered pits).

or **ladder-like** (fig. 257), when the thickening matter or lignin is deposited transversely in the form of rods or rungs of a ladder, and hence the name scalariform or ladder-like. (4) **Reticulate** or **netted** (fig. 258), when the thickening takes the form of a network. (5) **Pitted** (figs. 259-60), when the whole inner surface of the cell-wall is more or less uniformly thickened, leaving here and there some small unthickened areas or cavities. These unthickened areas are called **pits**, and are of two kinds, viz. (a) **simple pits** and (b) **bordered pits**.

Pits are formed in pairs lying against each other on the opposite sides of the wall. When the area of a pit is uniform throughout its whole depth, it forms a simple pit (figs. 261-62); and when this area is unequal, broader towards the wall and narrower towards the cavity of the cell, more or less like a funnel without the stem, it forms a bordered pit (fig. 263). In the bordered pit the adjoining thickening matter of the wall grows inwards and arches over the pit from all sides forming an overhanging border and hence the name 'bordered' pit. The portion of the middle lamella crossing the pits becomes thickened and is known as the **torus** (fig. 263 b-c).

Simple Pits. FIG. 261. A cell in section showing simple pits in its wall; *P*, pit; *C.W.*, cell-wall; *M.L.*, middle lamella.

name 'bordered' pit. The portion of the middle lamella crossing the pits becomes thickened and is known as the **torus** (fig. 263 b-c).

Chemical Nature of the Cell-wall. The cell-wall consists of a variety of chemical substances, of which cellulose is very conspicuous; but as the cell grows older, it undergoes chemical changes and variety of new substances are formed. Certain mineral matters are also often introduced into the cell-wall.

(1) **Cellulose.** The wall of the young cell is composed of a substance, called **cellulose**, which is an insoluble carbohydrate. Associated with cellulose there is some amount of pectin which acts as a cementing material holding together the cells of the plant body very much like cement in a brick wall. Cellulose is universally present in all green plants, particularly in their soft parts and in all their living cells. It is a soft, elastic and transparent substance, and is readily permeable by water. Walls made up of cellulose are usually thin so that water and soluble food materials can pass in and out. It is represented by the formula $(C_6H_{10}O_5)_n$, the value of n not being known. Cellulose is a very important substance. It is used as food by herbivorous animals; it cannot, however, be digested by human beings. Articles like paper, gun-cotton, celluloid and artificial silk are prepared from it. Cotton and linen are pure cellulose, while hemp is a mixture of cellulose and lignin.

(2) **Lignin.** Lignin is a hard and chemically complex substance. It is found in the hard and woody tissues of plants. Lignified tissues are thick-walled and dead. Although hard, lignin is permeable by water. The water-conducting vessels are all lignified. Most of the vegetable (textile) fibres are also lignified. Cotton fibres, however, are made of cellulose. The function of lignified tissues is mechanical, i.e. they contribute to the rigidity of the plant body.

(3) **Cutin.** Cutin is a waxy substance. It forms a definite thick or thin layer, called the **cuticle**, on the skin of the stem and the leaf. It makes the cell-wall impermeable or very slightly permeable by water. Its function is to prevent or check evaporation of water from the exposed surfaces of the plant.

(4) **Suberin.** Suberin is a fatty substance and occurs in the walls of cork cells. The cells of the bottle cork are suberized. Suberin makes the cell-wall almost impermeable by water and, therefore, like the cutin it also prevents or checks evaporation of water.

(5) **Mucilage.** Mucilage is a slimy substance. Its property is that it absorbs water freely and retains it. When dry it is very hard and horny, but when wet it forms a viscous mass. Mucilage is abundant in the leaves of Indian aloe, flowers of China rose, fruits of lady's finger, and seeds of linseed, *Plantago* (B. ISOBGUL ; H. ISOBGOL), etc.

Various mineral crystals may also be introduced into the cell-wall; these are mostly crystals of silica, calcium oxalate and calcium carbonate (see figs. 269-73). In the majority of fungi, and sometimes also in algae, the cell-walls are made up of a substance, called *chitin*—a substance allied to cellulose. *Chitin*, however, is peculiar to animals.

Micro-chemical Tests of the Cell-wall

NON-LIVING CELL-CONTENTS

There is a variety of chemical compounds formed in the plant body and stored up in certain cells. There are three main groups of them, viz. (I) **reserve materials**, (II) **secretory products**, and (III) **waste products**.

I. RESERVE MATERIALS

These are substances manufactured by the protoplasm and stored up by it in particular cells, and later utilized by it as *food* for its *nutrition*. Many of them occur in solution in the cell-sap; others are deposited in solid form in the cytoplasm. There are three main groups of them, viz. (1) **carbohydrates**, (2) **nitrogenous materials**, and (3) **fats and oils**.

(1) **Carbohydrates.** All carbohydrates contain carbon, hydrogen and oxygen. Of these, hydrogen and oxygen occur in the same proportion as they do in water, i.e. H_2O . When these substances are heated the water escapes and the carbon is left behind as a black mass. Some carbohydrates are soluble in water, e.g. sugars and inulin, while others are insoluble, e.g. starch and glycogen.

(1) **Sugars.** There are various kinds of sugars formed in plants. Of these, **grape-sugar** or **glucose** is chiefly found in grapes, and **cane-sugar** or **sucrose** in sugarcanes and beets. Grape-sugar is the simplest of all carbohydrates and is formed

in the leaf by chloroplasts *in the presence of sunlight*. Other forms of carbohydrates are derived from it. Commonly all the glucose formed in the leaf becomes converted into starch, an insoluble carbohydrate. At night this starch is reconverted into sugar which then travels to the storage organs where it is again converted into starch by leucoplasts. The chemical formula of grape-sugar is $C_6H_{12}O_6$, and that of cane-sugar $C_{12}H_{22}O_{11}$. Glucose contents of grapes are 12-15% or more; sucrose contents of sugarcanes 10-15% and of beet roots 10-20%.

Test for Glucose. Add **Fehling's solution** or an alkaline solution of **copper sulphate** to it, boil, and a yellowish red precipitate of cuprous oxide is formed. **Test for Sucrose.** Boil sucrose solution with 1 or 2 drops of **sulphuric acid**, and then try the test for glucose.

(2) **Inulin** (fig. 264). Inulin is a soluble carbohydrate, and occurs in solution in the cell-sap. When required for nutrition it is converted into a form of sugar (fruit-sugar). Inulin is present in the tuberous roots of *Dahlia* and some other plants.

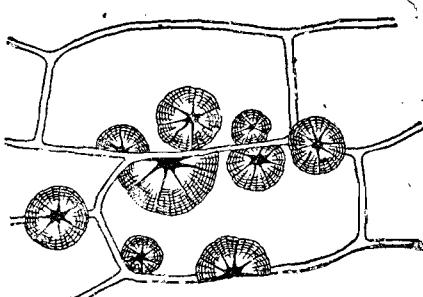

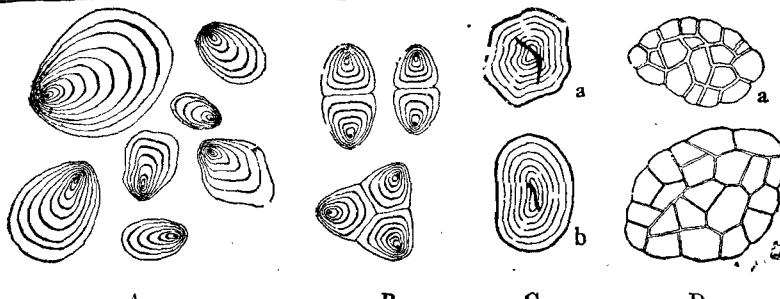

FIG. 264. Inulin crystals in the tuberous root of *Dahlia*.

When pieces of *Dahlia* roots are kept in alcohol or glycerine for 6 or 7 days, preferably more, inulin becomes precipitated in the form of spherical crystals (really aggregates of crystals). Under the microscope fully-formed inulin crystals are seen to be star- or wheel-shaped, and half-formed ones more or less fan-shaped. These crystals are deposited mostly across the cell-walls, and occasionally only in the cell-cavity. Sometimes these crystals are so large that they extend through many cells. Inulin has the same chemical composition as starch viz. $(C_6H_{10}O_5)_n$.

(3) **Starch** (fig. 265). This is an insoluble carbohydrate and occurs in the form of minute grains. Starch grains occur as a reserve food in all green plants in their storage organs. Rice, wheat, maize and millets which constitute the staple food of mankind are specially rich in starch. Starch grains may be oval, spherical, rounded and flat, or polygonal. They also vary very much in size, the largest known being about

100 microns (or $1/10$ mm.) in length, as in the rhizome of *Canna*, and the smallest about 5 microns (or $1/200$ mm.) in length, as in rice. In potato they are of varying sizes. Starch is always derived from sugar, either in the leaf by the chloroplasts or in the storage organ by the leucoplasts. When required for nutrition starch is converted into sugar.

Starch Grains. FIG. 265. A, simple eccentric grains in potato; B, compound grains in the same; C, a, simple concentric grain in maize; b, ditto in pea; D, a, compound grain in rice; b, ditto in oat.

In the starch grain a dark, roundish or elongated spot may be seen; this is the point of origin of the grain and is known as **hilum**. Around the hilum a variable number of strata (i.e.

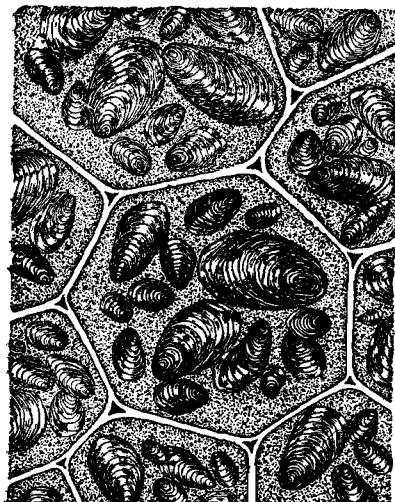

FIG. 266

Starch Grains (contd.). FIG. 266. Eccentric grains in a potato tuber.
FIG. 267. Concentric grains (and small granules of protein) in a cotyledon of pea.

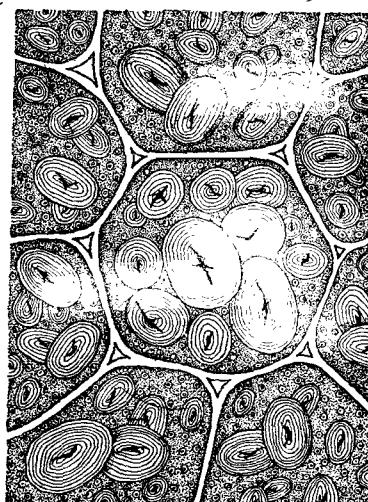

FIG. 267

layers) of different densities are alternately deposited. Each starch grain has thus a *stratified* appearance. In some grains, as in those of potato, the layers are laid down on one side of the hilum; such starch grains are said to be **eccentric**. In others, as in those of pea, the layers are deposited concentrically round the hilum; such starch grains are said to be **concentric**. Commonly, as in potato and pea, starch grains occur singly with one hilum, when they are said to be **simple**; sometimes, however, two or more grains occur together in a solid group with as many hilae as there are grains in it; this group then is said to form a **compound grain**, as in rice and oat (fig. 265D). A few compound grains are also sometimes formed in potato (fig. 265B). Starch has the same chemical composition as cellulose and inulin, viz. $(C_6H_{10}O_5)_n$. It is insoluble in water and alcohol. Rice contains 70-80% of starch; wheat about 70%; maize about 68%; barley 60-65%; arrow-root 20-30%; and potato 20%. *unicellular for*

Test. It turns **blue** to **black** when treated with **iodine solution**, the density of the colour depending on the strength of the reagent. *Glycogen*

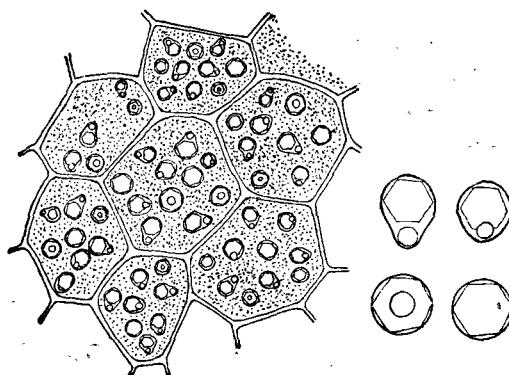

(4) **Glycogen.** This is a very common form of carbohydrate occurring in fungi. In yeast (see fig. 400), a unicellular fungus, it occurs to the extent of about 30% of the dry weight of the plant. It is not found in higher plants but is widely distributed among animals and is, therefore, sometimes called 'animal starch'. It occurs in the form of granules in the cytoplasm of the cell. Glycogen dissolves in hot water. It is coloured **reddish brown** with iodine solution. Its chemical formula is $(C_6H_{10}O_5)_n$.

2. **Nitrogenous Materials.** The nitrogenous reserve materials that are stored up in plants for their use as food are the various kinds of proteins and amino-compounds (amines and amino-acids).

(1) **Proteins.** Proteins are very complex, organic, nitrogenous substances containing carbon, hydrogen, oxygen and nitrogen, and also often sulphur and sometimes phosphorus. Proteins are very important as food being the source of nitrogen, and they also form an integral part of protoplasm. There are various kinds of them found in the plant body, particularly in their storage organs. They are mostly insoluble in water but all are soluble in strong acids and alkalis. A common form of insoluble or sparingly soluble protein, abundantly found in the endosperm of the castor seed, is the **aleurone**.

grain (fig. 268). Each aleurone grain is a solid, ovate or rounded body, and encloses in it a large crystal-like body, known as the **crystalloid**, and a small rounded mineral body, called the

FIG. 268.
Aleurone grains in the
endosperm of castor seed ;
right, a few grains
magnified. Note
the crystalloid and the
globoid in them.

globoid. The crystalloid is protein in nature, while the globoid is a double phosphate of calcium and magnesium. The occurrence of crystalloid and globoid is not always constant in the aleurone grain. Aleurone grains vary in size. When they occur with starch they are very small, as in pea; but in oily seeds they are very much larger, as in castor.

Fatty seeds usually contain a higher percentage of proteins than starchy seeds, e.g. rice contains only 7% of proteins, wheat 12%, while sunflower seeds contain proteins as high as 30%. Starchy seeds of leguminous plants, however, contain as high a percentage of proteins as fatty seeds, e.g. in the pulses there is an average of about 25% of proteins; in soybean (*Glycine max*) protein contents vary from 42-47%.

Average percentage composition may be given thus : carbon—50-54%; hydrogen—about 7%; oxygen—20-25%; nitrogen—16-18%; sulphur—0.4%; and phosphorus—0.4%.

Tests for Proteins. (1) Proteins are coloured yellowish brown with strong **iodine solution**. (2) **Xanthoproteic reaction**—add some strong nitric acid and a white precipitate is formed; on boiling it turns yellow. After cooling add a little strong ammonia and the yellow colour changes to orange.

(2) **Amino-compounds.** Amino-acids and amines are the simplest forms of all nitrogenous food materials, and occur in solution in the cell-sap. They are found abundantly in the growing regions of plants, less frequently in storage tissues. When translocation is necessary, proteins become converted into amines and amino-acids. They travel to the growing regions where the protoplasm is very active, and are directly assimilated by it. They are also the initial stages in the for-

mation of proteins. They contain carbon, hydrogen, oxygen and nitrogen, and sometimes also sulphur.

3. Fats and Oils. Fats and oils occur to a greater or less extent in all plants. They occur in the form of minute globules in the cytoplasm of the living cells. In the 'flowering' plants often special deposits of them are found in seeds and fruits. But in starchy seeds and fruits there is very little of them. Fats and oils are composed of carbon, hydrogen and oxygen, but the latter two do not occur in the same proportion as they do in water—the proportion of oxygen being always much less than in the carbohydrates. They are insoluble in water, but very readily soluble in ether, petroleum and chloroform. Comparatively few of them are soluble in alcohol, e.g. castor oil. Fats are synthesized in living bodies from fatty acids and glycerine under the action of the enzyme *lipase*. Both these products, viz. fatty acids and glycerine, are derived from carbohydrates (sugar and starch) during respiration. Fats and oils form an important reserve food with a considerable amount of energy stored in them. Their energy value is more than double that of the carbohydrates. When fats are decomposed the energy stored in them is liberated and made use of by the protoplasm for its manifold activities. Digestion of fats into fatty acids and glycerine is also brought about by the enzyme *lipase*. Fats that are liquid at ordinary temperature are known as 'oils'. In plants fats are usually present in the form of oils.

A large number are used for food, for manufacture of soap and oil-paints, for illumination, lubrication, etc., and are, therefore, of considerable economic importance, e.g. coconut oil, olive oil, sesame or gingelly oil, castor oil, groundnut oil, linseed oil, mustard oil, cotton seed oil, etc.

Tests for Fats and Oils. (1) The dry endosperm of castor or coconut burns when held over a flame. (2) It leaves a permanent greasy (oily) mark on a paper when rubbed on it. (3) Alcoholic solution of Sudan Red stains fats and oils red.

II. SECRETORY PRODUCTS

These include various products formed by the protoplasm, but not utilized by it for its nutrition and growth. They serve some special purposes.

i. Enzymes. These are soluble nitrogenous substances secreted by the protoplasm. Commonly they are known as the *digestive*

agents, and are meant to bring about digestion of food and also many other chemical changes.

2. **Colouring Matters.** Of the various colouring matters *chlorophyll* and *anthocyanin* are the most important.

3. **Nectar.** Nectar is secreted by many flowers in special cells or glands to attract insects for pollination ; the latter feed upon it, and incidentally carry the pollen grains from one flower to another.

III. WASTE PRODUCTS

These include various substances which are not of any vital use to the protoplasm, nor are they directly secreted by the latter, but are formed as mere *by-products*. There being no excretory system in plants, these waste products are deposited in the bark, old leaves, dead wood, and in other special cells away from the sphere of protoplasmic activity.

1. **Tannins.** These are a group of complex compounds widely distributed in plants. They commonly occur in single isolated cells or in small groups of cells in almost all parts of the plant body. They are abundant in the bark, heart-wood, many leaves, young and old, and many unripe fruits. As the fruits ripen tannins disappear ; they become converted into glucose and other substances. They are also abundant in the fruits of myrobalans. Tea leaves contain about 18% tannin. Catechu, a kind of tannin, is obtained from the heart-wood of *Acacia catechu*. Tannins are bitter substances, and that is why 'very strong' tea and fruits of myrobalans taste bitter. They are aseptic, i.e. free from the attack of parasitic fungi and insects. The presence of tannins makes the wood hard and durable. They are extensively used in tanning, i.e. converting hide into leather. They are also used for various medicinal purposes. They turn blue-black with an iron salt such as ferric chloride.

2. **Essential Oils.** These are volatile oils, and occur in *oil-glands* (see fig. 294 A) which appear as transparent spots in the leaves of sacred basil, shaddock, lemon, lemon grass, *Eucalyptus*, etc., in the skin of fruits like orange, lemon, shaddock, etc., and in the petals of flowers of many plants, as in rose, jasmines, etc. In all of them the essential oils have their own characteristic odours. They differ from fatty oils in their chemical composition as well as in being volatile. They are sufficiently

soluble in water to impart to it their taste and odour, but they are readily soluble in alcohol. There are some 200 essential oils of commercial value. Some of the common ones are lemon oil, eucalyptus oil, clove oil, lavender oil, sandalwood oil, thyme oil, etc.

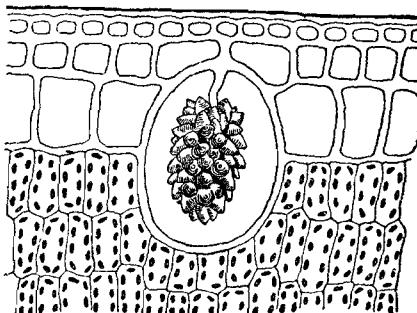

3. Resins. These are chemically complex substances mostly found in the stems of conifers (pine, for example) and occur in abundance in special ducts, known as resin-ducts (see fig. 279). They are yellowish solids, insoluble in water but soluble in alcohol, turpentine and methylated spirit. When present in the wood, resins add to its strength and durability. They occur associated with a small quantity of turpentine which is removed by distillation, and the residue in pure resin ; they may also occur associated with gums.

4. Gums. Gums are complex carbohydrates formed in various kinds of plants, being the decomposition products of cell-walls (cellulose). They are insoluble in alcohol but soluble in water, readily swell up in it, and form a viscous mass. They are found in many 'flowering' plants, and are of various kinds. *Acacia senegal* yields the best gum-arabic of commerce. Gums also occur in mixtures with resins.

5. Mineral Crystals. The common forms of crystals consist of silica, calcium carbonate and calcium oxalate. They occur either in the cell-cavity or in the cell-wall. Of them, crystals of calcium oxalate are most common, and are very widely distributed among various plants.

(1) **Silica** occurs as an incrustation on the cell-wall or lies embedded in it. It is most frequently found in the leaves of grasses and in *Equisetum*. Wheat straw contains about 72% of silica, rye straw about 50% and *Equisetum* about 71%.

(2) **Calcium carbonate** occurs as a big mass of small crystals in the leaf of India-rubber plant, banyan, etc. The crystals are deposited on a sort of stalk which is the ingrowth of the inner

Mineral Crystals. FIG. 269. Cystolith in the leaf of India-rubber plant.

epidermal wall. Finally the whole crystalline mass looks like a bunch of grapes suspended from a stalk, and is known as the **cystolith** (fig. 269).

(3) **Calcium oxalate** occurs as crystals of various forms. (a) **Raphides** (figs. 270-2) are needle-like crystals occurring singly

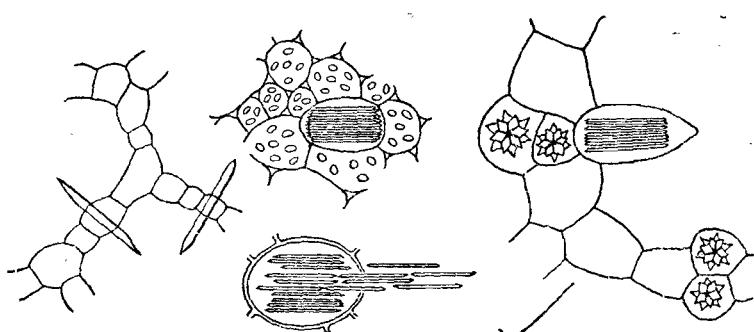

FIG. 270

FIG. 271

FIG. 272

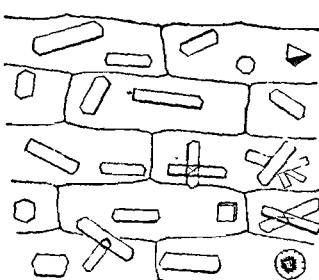

Mineral Crystals (*contd.*). FIG. 270. Solitary raphides (two) in the petiole of water hyacinth. FIG. 271. A bundle of raphides in the same; bottom, needles (raphides) shooting out. FIG. 272. Sphaero-crystals (four) and a bundle of raphides in taro (*Colocasia*).

or in bundles. They are found in most of the plants in smaller or larger quantities, but are specially common in water hyacinth, taro (B. KACHU ; H. KACHALU, *Amorphophallus* (B. OL ; H. KANDA), *balsam* (B. DOPATI ; H. GULMANDI), etc.

They are frequently shut off by a cell-wall from coming in contact with the protoplasm. (b) **Sphaero-crystals** (fig. 272) are clusters of crystals which radiate from a common centre, and hence have a more or less star-shaped appearance. They are found in taro (*Colocasia*), water lettuce (*Pistia*), etc. (c)

Octahedral, cubical, prismatic and rod-like crystals (fig. 273) of calcium oxalate are also common in plants; they can be readily seen in the dry scales of onion.

Tests. (a) 50% nitric acid (or hydrochloric or sulphuric acid) solution dissolves both calcium carbonate and oxalate crystals, but bubbles of carbon dioxide gas are evolved only in the case of carbonate crystals. (b) 30%

Mineral Crystals (*contd.*)
FIG. 273. Various forms of
calcium oxalate crystals in
the dry onion scale.

acetic acid solution readily dissolves calcium carbonate crystals only, but not the oxalate crystals.

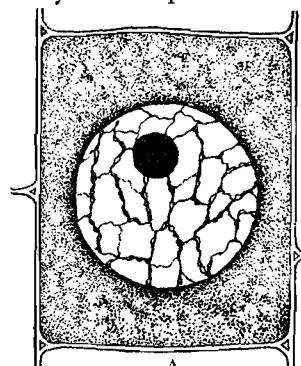

6. Latex. This is the milky juice found in latex cells and latex vessels (see figs. 292-93). Latex occurs as an emulsion consisting of a variety of chemical substances. Rod- or dumb-bell-shaped starch grains may often be found in the latex. It also sometimes contains some poisonous substances. The function of latex is not clear; perhaps in some way it is associated with nutrition, healing of wounds and protection against parasites and animals. Latex is often white and milky, as in banyan, peepul, jack, madar, oleander, *Euphorbia*, etc., sometimes coloured (yellow, orange or red), as in opium poppy, garden poppy, prickly poppy, etc.

7. Alkaloids. These are complex nitrogenous substances, and occur combined with some organic acids, mostly in seeds and roots of some plants. They have an intensely bitter taste and many of them are extremely poisonous. There are over 200 known alkaloids found in plants, e.g. quinine in *Cinchona*, nicotine in tobacco, morphine in opium poppy, caffeine in coffee and tea, strychnine in *nux-vomica*, etc.

FORMATION OF NEW CELLS

Plants begin their existence as a single cell. This divides and forms two cells ; these again divide, and the process continues, resulting in the development of the body of the plant. There are various methods by which new cells are formed in plants by division of the pre-existing cell. In all such cases it is the nucleus that divides first, and this is followed by the division of the cell.

1. Somatic Cell Division.¹ Cell division leading to the development of the vegetative body (soma) of the plant is known as somatic cell division. It includes the division of the nucleus, called mitosis (*mitos*, thread) or karyokinesis (*karyon*, nut

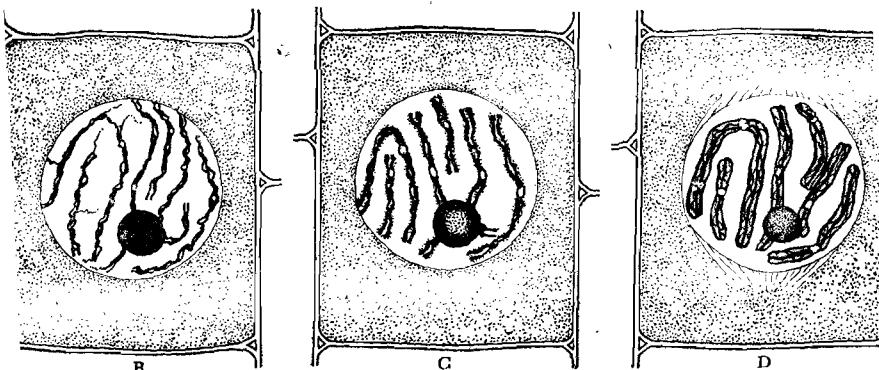

Mitosis. FIG. 274 A.
Metabolic nucleus.

¹ Fig. 274 A-J redrawn after fig. 40 in Fundamentals of Cytology by L. W. Sharp by permission of McGraw-Hill Book Company. Copyright 1943.

or nucleus; *kinesis*, movement or **indirect nuclear division**, and the division of the cytoplasm, called **cytokinesis**. It occurs in the growing regions, as in the root-tip and the stem-tip. **Mitosis** (fig. 274). In this process the nucleus (A) passes through a complicated system of changes which may conveniently be divided into four phases.

First Phase or Prophase. The first sign of the prophase is the appearance of a number of separate, slender, crooked threads, called **chromosomes** (B). The chromosomes, particularly the longer ones, are more or less spirally coiled. The individual chromosomes are always longitudinally double, with the two threads, called **chromatids**, remaining adpressed against each other throughout their length. Chromosomes are composed of nucleoproteins. As prophase proceeds the chromosomes

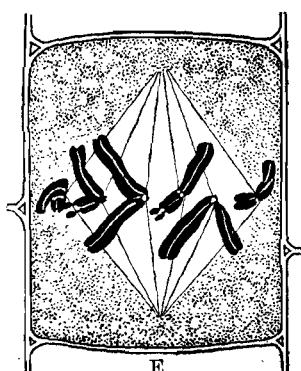

Mitosis (contd.). FIG. 274 B-D. Prophase.

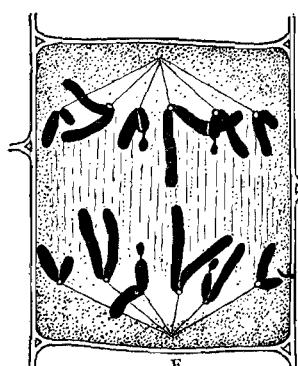

relax their coils and thicken somewhat (C). Their double nature becomes more apparent. As prophase advances a chromosomal substance accumulates in a sheath or matrix round each chromosome and the chromatids become closely coiled in it (D). In well-fixed chromosomes some unstained gaps or constrictions are seen; these are the attachment regions, called **centromeres**. The nucleoli lose their staining power and disappear completely. The nucleus then rapidly passes into the next stage, the metaphase, through a complicated series of changes.

Second Phase or Metaphase. The nuclear membrane disappears and a spindle-like body known as the **nuclear spindle** is formed (E). The spindle may be formed entirely out of the

nuclear sap; or, it may appear, commonly in root-tips, as two opposite polar caps outside the nuclear membrane (as in D). The membrane then disappears and the spindle extends into the nuclear area. The chromosomes move to the equatorial plane of the spindle and stand there clearly apart from one another. At this stage the chromatids come even more closely together. From the centromeres of each pair of chromatids fibre-like extensions, called *tractile fibres*, are formed towards the opposite poles through the nuclear spindle. The number of chromosomes is normally constant for a particular species of plants and this number is also normally even, expressed as 2_n (or 2_x) or diploid. Chromosome numbers cover a wide range but 24 seem to be a common figure.

Mitosis (contd.).
FIG. 274 E. Metaphase.

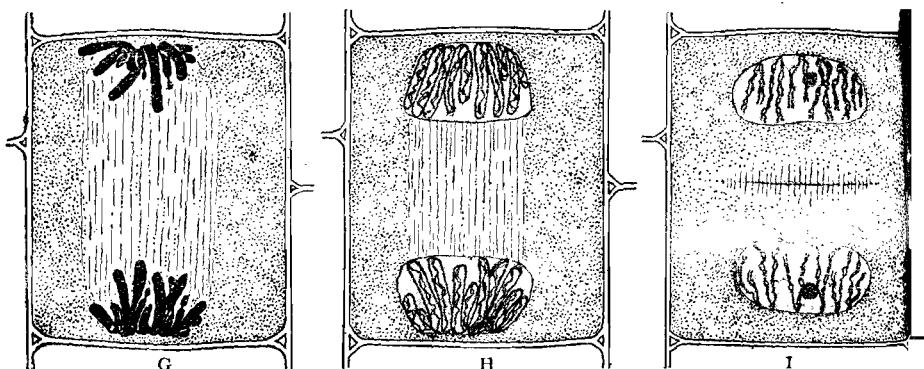

Mitosis (contd.).
FIG. 274 F. Anaphase.

Third Phase or Anaphase. At the end of the metaphase the centromeres of each pair of chromatids appear to repel each other. They diverge and move ahead towards the two opposite poles along the course of tractile fibres (F). The chromatids soon become separated from each other.

Fourth Phase or Telophase. At each pole the chromatids (now regarded as chromosomes) form a close group (G). The nuclear spindle disappears and so does the

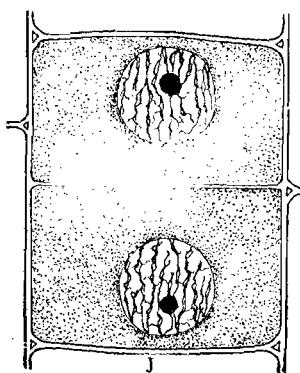

matrix. A nuclear membrane is formed round each group of chromosomes (H). Nucleoli reappear at definite points on certain chromosomes. The chromosomes reorganize themselves as two nuclei. The nuclear sap reappears and each nucleus increases in size (I). It passes into the metabolic stage or prepares for the next division.

Cytokinesis. This is the division of the cytoplasm by the formation of a new cell-wall in the equatorial region. This process,

Mitosis (contd.). FIG. 274 G-I. Telophase.

known as the cell-plate method, is the usual one in the vegetative cell. It usually begins in the telophase when new cellulose particles are gradually deposited in the equatorial zone, and soon these particles fuse together to form a delicate membrane, dividing the cytoplasm into two new cells (J).

Mitosis (contd.).
FIG. 274 J. Cytokinesis.

hereditary characters and because of even distribution of chromosomal substance the two daughter nuclei possess all the characters and qualities of the mother nucleus.

2. Meiosis or Reduction Division (fig. 275). Meiosis (*meiosis*, diminution) is a complicated process of nuclear division by which the chromosome number is reduced to half in the four daughter nuclei so formed by this process. The reduced chromosome number is expressed as *haploid* or n (or α). For example, if there be 12 chromosomes in the mother nucleus there will be only half this number, i.e. 6 chromosomes in the daughter nuclei. Meiosis is completed in two divisions. In this process the mother nucleus with $2n$ chromosomes divides twice to give rise to four nuclei in a group, each nucleus with n chromosomes. Of the two successive divisions it is only the first one that is reduction division, while the second one is mitotic.

Meiosis takes place in all plants reproducing sexually at a certain time in their life-cycle, most often in the formation of spores, as in all higher

cryptogams and 'flowering' plants, and sometimes in the formation of gametes, as in some algae. In green algae and many fungi reduction division takes place either immediately after fertilization or on the germination

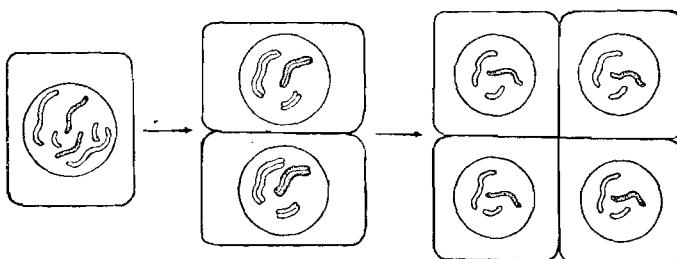

FIG. 275. Meiosis (diagrammatic). Note that the first division is reductional, while the second one is mitotic.

of the zygote. Wherever meiosis may occur in the life-cycle of a plant, it is universally true that all gametes have half the usual number of chromosomes. Then when sexual reproduction takes place, i.e. when two gametes (each with n chromosomes) fuse together the chromosome number becomes doubled ($n+n=2n$) in the zygote.

The significance of meiosis is that by this process the chromosome number is kept constant from generation to generation. If no reduction had taken place in the chromosome number at any stage of a plant the offspring would have an ever-increasing number of chromosomes and a peculiar composition of them resulting in new peculiar and distinct types of offspring since chromosomes are the bearers of hereditary characteristics, and meiosis is the mechanism for their transmission to the offspring.

3. Amitosis or Direct Nuclear Division (fig. 276). In this case the nucleus elongates to some extent and then it undergoes constriction, i.e. it becomes narrower and narrower in the middle or at one end, and finally it splits into two. The nuclei so formed may be of equal or unequal sizes. The direct nuclear division may or may not be followed by the division of the cell. Amitosis commonly occurs in certain lower algae and fungi. In the higher plants it is seen to occur in certain old cells here and there.

4. Free Cell Formation (fig. 277). This is a modification of indirect nuclear division. It differs from it in that the cell-wall is not formed immediately after the division of the nucleus. In this process by repeated mitotic divisions a large number of nuclei are formed. When the divisions of the nuclei cease, cytoplasm aggregates round them, and a cell-wall is formed round each nucleus. The formation of the cell-wall gradually proceeds from one side to the other, result-

ing in a regular tissue (combination of cells). The endosperm, i.e. the food storage tissue of the seed, is formed by this method.

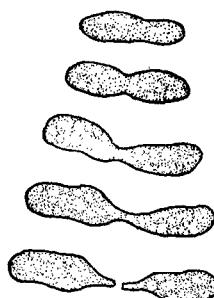

FIG. 276

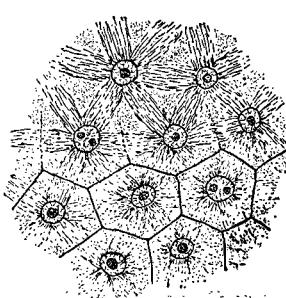

FIG. 277

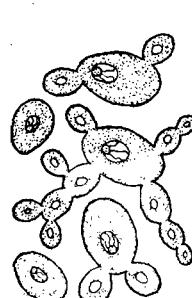

FIG. 278

FIG. 276. Amitosis or direct nuclear division. FIG. 277. Free cell formation in the development of endosperm. FIG. 278. Budding in yeast.

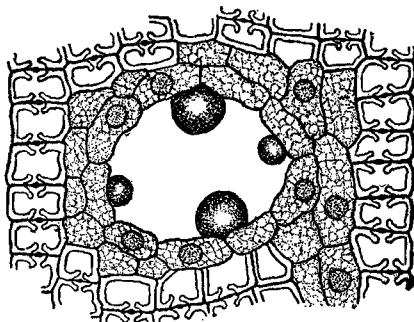

5. **Budding** (fig. 278). This is seen in yeast—a unicellular fungus. In this plant the cell forms one or more tiny outgrowths on its body. The nucleus undergoes direct division (amitosis) and splits up into two. One of them passes on to one outgrowth. The outgrowth increases in size and is ultimately cut off from the mother yeast as a new independent cell (a new yeast plant). This process of cell formation is known as *budding*. Often budding continues one after the other so that chains and even sub-chains of cells are formed. Ultimately all the cells separate from one another.

INTERCELLULAR SPACES AND CAVITIES

Intercellular Spaces. When the cells are young they remain closely packed without any empty space or cavity between them; but as they grow, their walls split at certain points, giving rise to small cavities or empty spaces; these are intercellular spaces. They remain filled with air or water.

Schizogenous Cavities. Bigger cavities are also often formed by the splitting up of common walls and the separation of masses of cells from one another; these are schizogenous (*schizein*, to split) cavities. Intercellular spaces and these cavities form an intercommunicating system so that gases and liquids can easily diffuse from one part of the plant body to the other. Most resin-ducts in plants are schizogenous cavities (fig. 279).

Lysigenous Cavities. Sometimes, during the development of a mass of cells, their walls break down and dissolve, and as a consequence large irregular cavities appear; these are known as lysogenous (*lysis*, loosening) cavities. These cavities are meant for storing up water, gases, essential oils, etc., and thus act as glands (see fig. 294A).

Schizogenous Cavity.

CHAPTER 2 The Tissue

Cells grow and assume distinct shapes to perform definite functions. Cells of the same shape grow together and combine into a group for the discharge of a common function. Each group of mature cells gives rise to a tissue. *A tissue is thus a group of cells or of vessels which are alike in form and function and have a common origin.* Tissues may primarily be classified into two groups: meristematic and permanent.

Meristematic Tissues (*meristos*, divided). These are composed of cells that are in a state of division or retain the power of dividing. These cells are either spherical, oval or polygonal in shape without any intercellular spaces; their walls thin and homogeneous; the protoplasm abundant and active with large nuclei; and the vacuoles small or absent. Meristematic tissues may be apical and lateral: (a) the apical meristem lies at the apex of the stem and the root (see figs. 295-96) and gives rise to primary permanent tissues, while (b) the lateral meristem, e.g. cambium (see figs. 303-4), lies among masses of permanent tissues and gives rise to secondary permanent tissues.

Permanent Tissues. These are composed of cells that have lost the power of dividing, having attained their definite form and size. They may be living or dead and thin-walled or thick-walled. Permanent tissues are formed by differentiation of the cells of the meristems and may be **primary** or **secondary**.

The primary permanent tissues are derived from the apical meristems of growing regions and the secondary permanent tissues from the lateral meristems.

PRIMARY PERMANENT TISSUES

Classification. Primary permanent tissues may be classified as *simple* and *complex*. A simple tissue is made up of one type of cells forming a homogeneous or uniform mass, and a complex tissue is made up of more than one type of cells working together as a unit. To these may be added another kind of tissue—the secretory tissue.

I. SIMPLE TISSUES

1. **Parenchyma** (fig. 280). Parenchyma consists of a collection of cells which are more or less isodiametric, that is, equally

FIG. 280

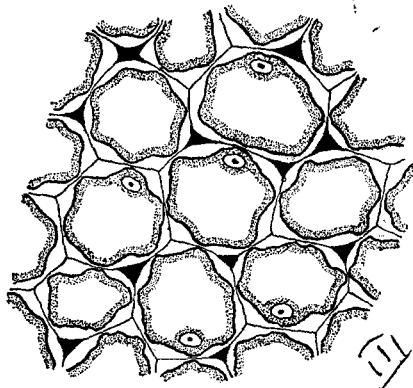

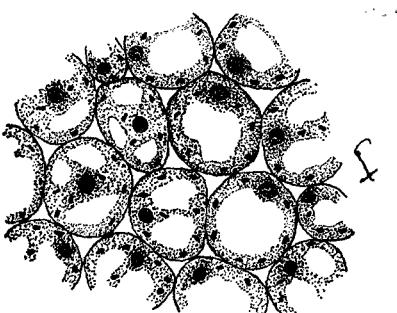

FIG. 281

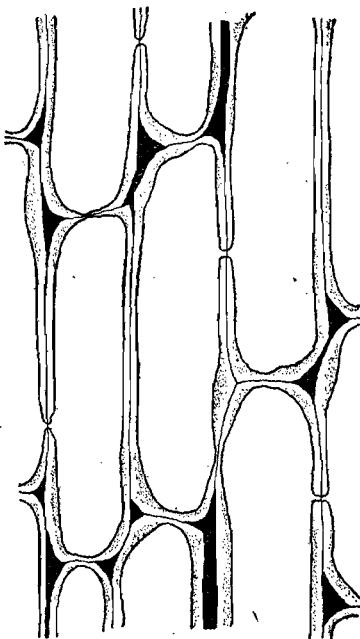

FIG. 282

FIG. 280. Parenchyma. FIG. 281. Collenchyma in transsection.
FIG. 282. Collenchyma in longitudinal section.

expanded on all sides. Typical parenchymatous cells are oval, spherical or polygonal in shape. Their walls are thin and made of cellulose; they are usually living. Parenchyma is of universal occurrence in all the soft parts of plants. Its function is mainly storage of food material. Parenchyma containing chloroplasts, often called *chlorophyllous*, manufactures sugar and starch. Star-like parenchyma with radiating arms, leaving a lot of air-cavities, is called *aerenchyma*, as in the petiole of banana and *Canna* (figs. 283-84) and also in many aquatic plants.

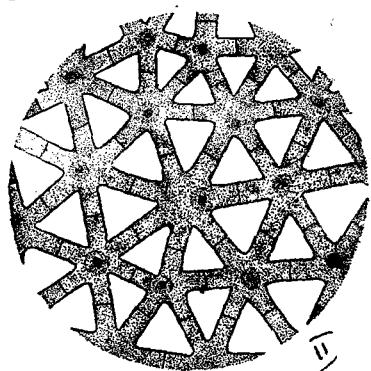

FIG. 283

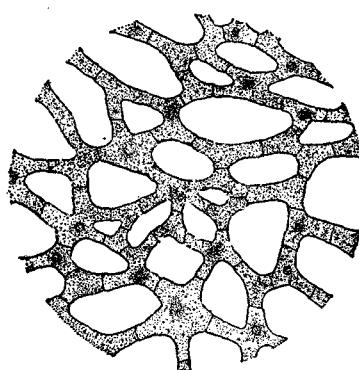

FIG. 284

FIG. 283. *Aerenchyma* in the petiole of banana. FIG. 284. The same in the petiole of *Canna*.

2. **Collenchyma** (figs. 281-82). This tissue consists of somewhat elongated cells with the corners or intercellular spaces much thickened with a deposit of cellulose and pectin. In a transverse section of the stem the cells, however, look circular or oval. Their walls are provided with simple pits here and there. Collenchyma occurs in a few layers under the skin (epidermis) of herbaceous dicotyledons, e.g. sunflower, gourd, etc. (see figs. 304 & 306). It is absent from the root and the monocotyledon except in special cases. The cells are living and often contain some chloroplasts. Being flexible in nature collenchyma gives tensile strength to the stem. Containing chloroplasts it also manufactures sugar and starch. Its functions are, therefore, both mechanical and vital.

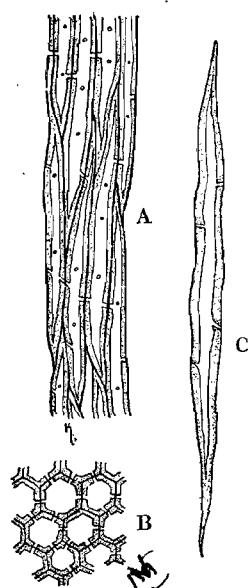

3. **Sclerenchyma** (fig. 285). Sclerenchyma (*scleros*, hard) consists of very long, narrow, thick-walled and lignified cells, usually pointed at both ends. They are fibre-like in appearance, and hence they are also called sclerenchymatous fibres,

or simply fibres. They have simple, often oblique, pits in their walls. The middle lamella is conspicuous in sclerenchyma.

Sclerenchymatous cells are found abundantly in plants, and occur in patches or definite layers. They are dead cells, and serve a purely mechanical function, that is, they give strength and rigidity to the plant body and thus enable it to withstand various strains. Their average length is 1 to 3 mm. but in the fibre-yielding plants such as hemp (B. & H. GANJA), Indian hemp (B. SHONE ; H. SAN), jute, rhea, flax, etc., these cells may be of excessive lengths ranging from 20 mm. to 550 mm. Such fibres are of commercial importance.

Sometimes here and there in the plant body special types of sclerenchyma may be developed. These are known as the **stone** or **sclerotic** cells (fig. 286). The cells are very thick-walled and strongly lignified, and are mostly isodiametric or irregular in shape or slightly elongated. Stone cells occur in hard seeds,

FIG. 285. Sclerenchyma; A, fibres as seen in longi-section; B, the same as seen in transection; and C, a single fibre.

shape or slightly elongated. Stone cells occur in hard seeds,

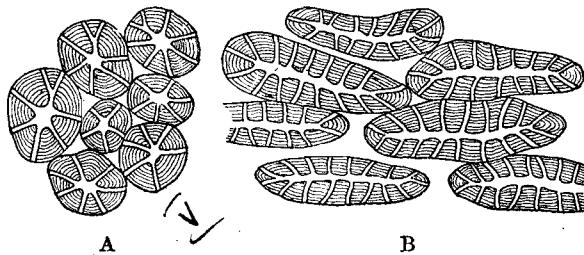

FIG. 286. Stone cells; A, as seen in transection; B, as seen in longi-section.

nuts and stony fruits. They contribute to the firmness and hardness of the part concerned. The flesh of pear is gritty because of the presence of stone cells in it.

II. COMPLEX TISSUES

1. **Xylem.** Xylem or wood is a conducting tissue and is composed of elements of different kinds, viz. (a) tracheids,

THE TISSUE

vessels or tracheae (sing. trachea), (c) wood fibres, and (d) wood parenchyma. Xylem as a whole is meant to conduct water and mineral salts upward from the root to the leaf, and to give mechanical strength to the plant body. Except wood parenchyma all other xylem elements are lignified, thick-walled and dead.

(a) **Tracheids** (figs. 287-88). These are elongated, tube-like dead cells with hard, thick and lignified walls and a large cell-cavity. Their ends are commonly tapering or oblique. Their walls are usually provided with one or more rows of bordered pits. Tracheids may also be annular, spiral, scalariform or pitted (with simple pits). In transverse section they are mostly angular, either polygonal or rectangular. Tracheids (and not vessels) occur alone in the wood of ferns and gymnosperms, whereas in the wood of angiosperms they occur associated with the vessels. Being lignified and hard, tracheids give strength to the plant body but their main function is conduction of water from the root to the leaf.

(b) **Vessels or Tracheae** (fig. 289). Vessels are rows of elongated tube-like dead cells, placed end to end, with their transverse or end-walls dissolved. A vessel or trachea is thus very much like a series of water-pipes forming a pipe-line. Their walls are thickened in various ways, and according to the mode of thickening vessels have received their names such as **annular**, **spiral**, **scalariform**, **reticulate**, and **pitted**. Associated with the vessels are often found some tracheids. Vessels and tracheids form the main tissues of the wood or xylem of the vascular bundle (see fig. 302). They have large cell-cavities

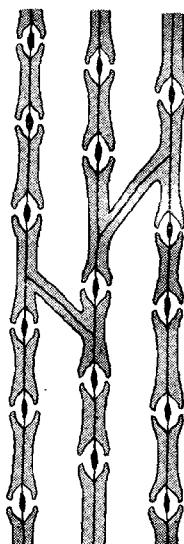

FIG. 287

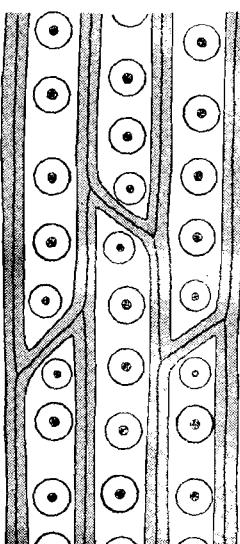

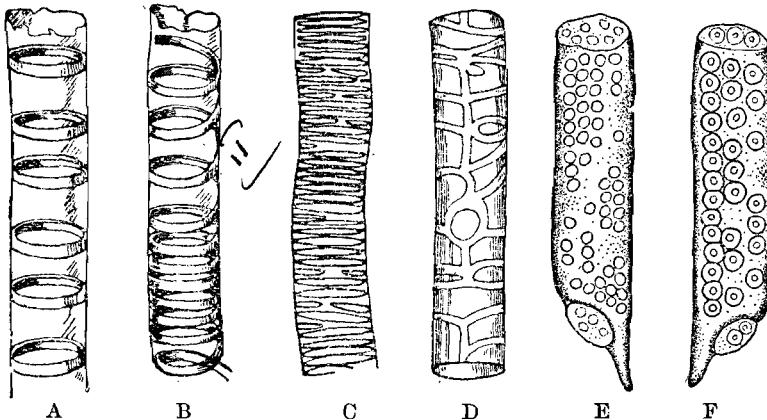

FIG. 288

Tracheids with Bordered Pits. FIG. 287. Pine stem in radial section. FIG. 288. The same in tangential section.

which serve for conduction of water and mineral salts from the roots to the leaves. They are dead, thick-walled and lignified,

Kinds of Vessels. FIG. 289. *A*, annular; *B*, spiral; *C*, scalariform; *D*, reticulate; *E*, a vessel with simple pits; *F*, a vessel with bordered pits.

and as such they also serve the mechanical function of strengthening the plant body.

(c) **Wood Fibres.** Sclerenchymatous cells associated with wood or xylem are known as wood fibres. They occur abundantly in woody dicotyledons and add to the mechanical strength of the xylem and the plant body as a whole.

(d) **Wood Parenchyma.** Parenchymatous cells associated with xylem together form the wood parenchyma. The cells are alive, thin-walled and generally abundant. The wood parenchyma assists, directly or indirectly, in the conduction of water upwards through the vessels and the tracheids ; it also serves for food storage.

2. Phloem. Phloem or bast is another conducting tissue, and is composed of the following elements: (a) **sieve-tubes**, (b) **companion cells**, (c) **phloem parenchyma**, and (d) **bast fibres** (rarely). Phloem as a whole is meant to conduct prepared food materials from the leaf to the storage organs and the growing regions.

(a) **Sieve-tubes** (figs. 290-91). Sieve-tubes are slender, tube-like structures composed of elongated cells, placed end on end. Their walls are thin and made of cellulose ; each transverse wall is, however, perforated by a number of pores. It then looks very much like a sieve, and is called the **sieve-plate**. In winter, the sieve-plate is covered by a thin pad, called

callus or callus pad. In spring, when the active season begins,

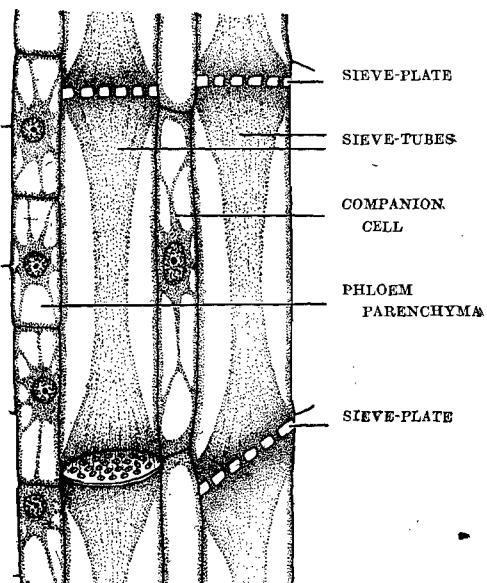

FIG. 290. Sieve tissue in longitudinal section.

the callus gets dissolved. In old sieve-tubes the callus forms a permanent deposit. The sieve-tube contains no nucleus, but has a lining layer of cytoplasm which is continuous through the pores. Sieve-tubes carry prepared food materials—proteins and carbohydrates—from the leaves to the storage organs and the growing regions of the plant body. A heavy deposit of food material is found on either side of the sieve-plate with a narrow median portion.

(b) **Companion Cells.** Associated with each sieve-tube and connected with it by simple pits there is a thin-walled, elongated cell, known as the companion cell. It is living, containing protoplasm and a large elongated nucleus. The companion cell is present only in angiosperms.

(c) **Phloem Parenchyma.** There are some parenchymatous cells in the phloem. These are living, and in shape often cylindrical. Phloem parenchyma, however, is mostly absent in monocotyledons.

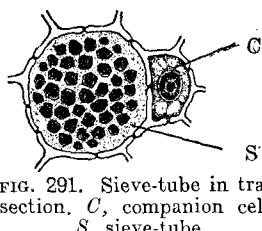

FIG. 291. Sieve-tube in trans-section. C, companion cell; S, sieve-tube.

(d) **Bast Fibres.** Sclerenchymatous cells occurring in the phloem or bast are known as bast fibres. These are generally absent in the primary phloem but are of frequent occurrence in the secondary phloem.

III. SECRETORY TISSUES

1. **Laticiferous Tissue.** This consists of thin-walled, greatly elongated and much branched ducts (figs. 292-3) containing a milky juice, known as *latex* (see p. 149). Laticiferous ducts are of two kinds: latex vessels and latex cells. They contain numerous nuclei which lie embedded in the thin lining layer of protoplasm. They occur irregularly distributed in the mass

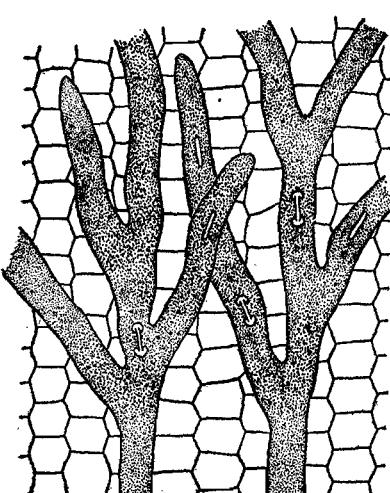

FIG. 292

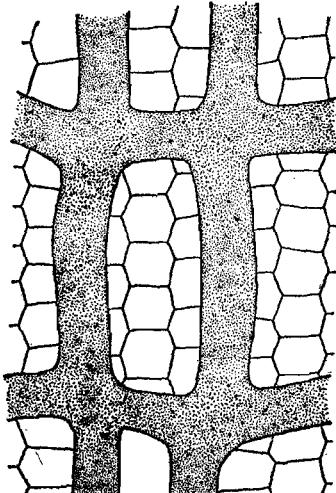

FIG. 293

Laticiferous Tissue. FIG. 292. Latex cells. FIG. 293. Latex vessels.

of parenchymatous cells. The function of laticiferous ducts is not clearly understood. They may act as food-storage organs or as reservoirs of waste products. They may also act as translocatory tissues.

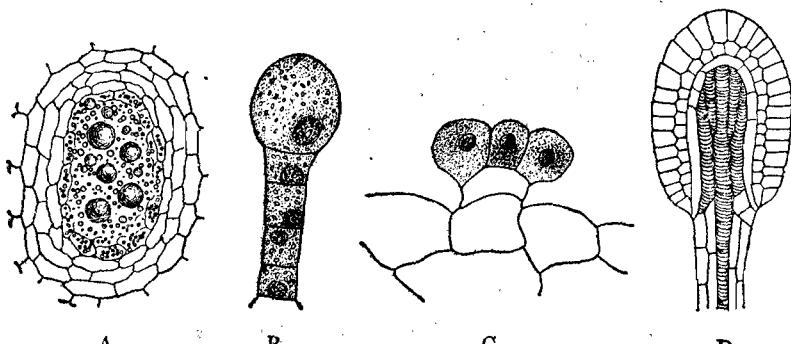

Latex vessels (fig. 293) are rows of more or less parallel ducts, connected with one another by the fusion of their branches, forming a network. Latex vessels are found in the poppy family, e.g. opium poppy, garden poppy and prickly poppy, and also in some species of the sunflower family, e.g. *Sonchus*.

Latex cells (fig. 292), on the other hand, although much branched like the latex vessels, are really single or independent

units. They branch profusely through the parenchymatous tissue of the plant, but *without fusing together to form a network*. Latex cells are found in madar, *Euphorbia* (B. & H. SIJ), oleander, periwinkle, *Ficus* (e.g. banyan, fig, peepul), etc.

2. Glandular Tissue. This tissue is made of glands which are special structures containing some secretory or excretory products. Glands may consist of single isolated cells or small groups of cells with or without a central cavity. They are of various kinds and may be internal or external.

Internal glands are (1) oil-glands (fig. 294 A) secreting essential oils, as in the fruits and leaves of orange, lemon, pummelo, etc.; (2) mucilage-secreting glands, as in the betel leaf; (3) glands secreting gum, resin, tannin, etc.; (4) digestive glands secreting enzymes or digestive agents; and (5) special water-secreting glands at the tips of veins.

Glands. FIG. 294. A, an oil-gland of orange skin; B, a glandular hair of *Boerhaavia* fruit; C, a digestive gland of butterwort (insectivorous); D, a digestive gland of sundew (insectivorous).

External glands are commonly short hairs tipped by glands. They are: (1) water-secreting hairs or glands; (2) glandular hairs (fig. 294 B) secreting gummy substances, as in tobacco, *Plumbago* (B. CHITA; H. CHITRAK), and *Boerhaavia* (B. PUNARNAVA; H. THIKRI); (3) glandular hairs secreting irritating, poisonous substances, as in nettles (fig. 137); (4) honey glands or nectaries, as in many flowers; and (5) enzyme-secreting glands (figs. 294 C-D), as in carnivorous plants.

Distribution of Strengthening or Mechanical Tissues. The distribution of mechanical tissues in the plant body is determined by several factors. From a purely mechanical standpoint the principle of distribution is as follows. Stems have to

bear the weight of the upper parts, and are swayed back and forth by the wind. They are, therefore, subjected to alternate stretching and compressing. The best position for strengthening tissues in stems, therefore, is close to the periphery, either in the form of a cylinder or in patches. Roots, on the other hand, are subjected to the pulling force exerted by the swaying stem and also to the compressing force exerted by the surrounding soil. These forces are met by roots by the development of a solid wood cylinder in or around the centre.

Collenchyma and sclerenchyma including wood fibres and bast fibres are the two most important tissues concerned in the strengthening of the plant body. Their distribution may be studied with reference to the sunflower stem (see fig. 304) and the maize stem (see fig. 306).

Roots develop sclerenchyma less frequently and they are wanting in collenchyma. Here the lignified wood vessels and tracheids give the necessary strength. Later on wood fibres develop in the secondary wood and contribute materially to the mechanical strength of the root. In many monocotyledonous roots, as in aroids, the pith is sclerenchymatous. Sometimes, as in orchids, the conjunctive tissue is also sclerenchymatous.

Distribution of sclerenchyma in the leaf is rather irregular. It is commonly associated with the vein or vascular bundle, or it may occur as patches here and there.

APICAL MERISTEM

i. **Stem Apex** (fig. 295). A median longitudinal section through the apex of a stem, when examined under the microscope, shows that the apical meristem or growing region is composed of a mass of small, usually rounded or polygonal cells which are all alike and are in a state of division; these meristematic cells constitute the **promeristem**. The cells of the promeristem soon differentiate into three regions, viz., dermatogen, periblem and plerome. The cells of these three regions grow and give rise to primary permanent tissues in the mature portion of the stem. The section further shows on either side a number of outgrowths which arch over the growing apex; these are the young leaves of the bud, which cover and protect the tender growing apex of the stem.

(i) **Dermatogen** (*derma*, skin; *gen*, producing). This is the single outermost layer of cells. It passes right over the apex and

continues downwards as a single layer. The cells divide by *radial* walls only, i.e. at right angles to the surface of the stem, and increase in circumference, thus keeping pace with

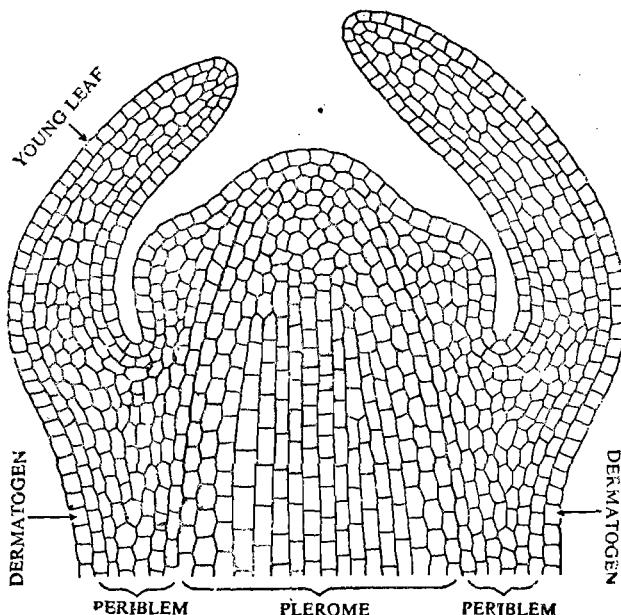

FIG. 295. Stem apex in longitudinal section.

the increasing growth in volume of the underlying tissues. The dermatogen gives rise to the skin layer or epidermis of the stem (see p. 167).

(2) **Periblem** (*peri*, around ; *blema*, covering). This lies internal to the dermatogen, and is the middle region of the apical meristem. At the apex it is single-layered but lower down it becomes multi-layered. It forms the cortex of the stem, which is often, particularly in dicotyledons, differentiated into hypodermis, general cortex and endodermis (see p. 170).

(3) **Plerome** (*pleres*, full). This lies internal to the periblem, and is the central region of the stem apex. At a little distance behind the apex certain groups or strands of cells show a tendency to elongate. These groups or strands of elongated cells are said to form the **procambium**. In a transverse section of the stem each procambium appears as a small group of cells which soon become differentiated into the elements of xylem and phloem, i.e. into a vascular bundle. A portion, however, remains undifferentiated, and it forms the cambium of the

vascular bundle. Plerome as a whole gives rise to the central cylinder or stele (see p. 172) as it is called, which in a dicotyledonous stem is differentiated into the pericycle, medullary rays, pith and the vascular bundles (see fig. 304 A-B).

2. Root Apex (fig. 296). A median longitudinal section through the apex of the root shows that it is covered over and

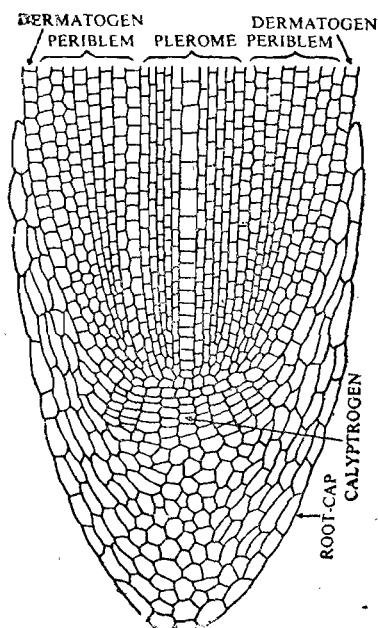

FIG. 296. Root apex in longitudinal section.

protected by a many-layered tissue which constitutes the **root-cap**. The apical meristem or growing region lies within and behind the root-cap (see fig. 41). The pro-meristem, as in the stem, early differentiates into three regions, viz. (1) dermatogen, (2) periblem, and (3) plerome. In many roots, however, these three regions are not clearly marked.

(1) **Dermatogen.** As in the stem, this also is single-layered, but at the apex it merges into the periblem; outside this the dermatogen cuts off many new cells, forming a small-celled tissue, known as the **calyptrogen** (*calyptra*, cap; *gen* producing). The calyptrogen is also

meristematic, and by repeated divisions of its cells gives rise to the **root-cap**. As the root passes through the hard soil, the root-cap often wears away but then it is renewed by the underlying calyptrogen. The walls of outer cells of the root-cap may be modified into mucilage which helps the root to push forward in the soil more easily. At a little distance from the root-tip the outermost layer bears a large number of *unicellular root-hairs*. The dermatogen continues upwards as a single outermost layer called the *epiblema*.

(2) **Periblem.** As in the stem, this also is single-layered at the apex and many-layered higher up. Periblem forms the middle region or cortex of the root (see fig. 309).

(3) **Plerome.** Its structure and function are practically the same as those of the stem. But here some procambial strands give rise to bundles of vessels (xylem) and others to bundles of sieve-tubes (phloem) in an alternating manner (see fig. 303 A). In many roots and stems, however, the apical meristem is not sharply separable into the three regions mentioned above particularly into the periblem and the plerome. In such cases the division is as follows : (1) **protoderm,** which corresponds to the dermatogen, (2) **procambium,** which forms isolated groups or strands of cells, as in the previous classification, and (3) **ground** or **fundamental meristem,** which fills up the remaining spaces. It is a combination of the periblem and the plerome (excluding the procambium).

CHAPTER 3 *The Tissue System*

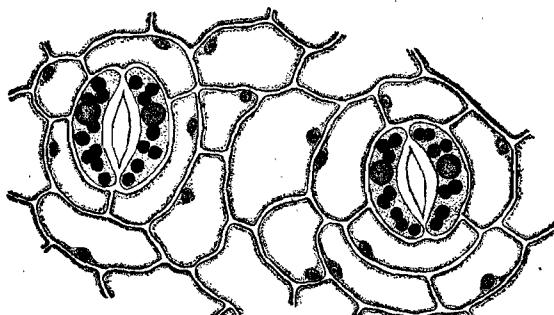

There exists in the higher plant a division of labour, and in response to this, tissues are arranged into three systems, each taking a definite share in the common life-work of the plant. Each system may consist of only one tissue or a combination of tissues which may structurally be of like or different nature, but perform a common function and have the same origin. The three systems are : (I) the epidermal tissue system, (II) the ground or fundamental tissue system, and (III) the vascular tissue system.

1. **The Epidermal Tissue System.** The epidermal tissue system consists mainly of a single outermost layer called the **epidermis** (*epi*, upon ; *derma*, skin) which extends over the entire surface of the plant body. At surface view the cells of the epidermis are somewhat irregular in outline (see fig. 297), but closely fitted together without intercellular spaces. They, however, appear more or less rectangular in transection. Epidermal cells are parenchymatous in nature with colourless cell-sap. In the leaves and young green shoots the epidermis possesses numerous minute openings called **stomata** (see fig. 297). The outer walls of the epidermis are often thickened and cutinized. The cutinized layer or the **cuticle** checks evaporation of water. In many plants the epidermis bears hairs of different kinds—soft, stiff, sharp, stinging, glandular, etc. *Functions.* The epidermis functions as a protective tissue. It protects the plant body against excessive evaporation of water, attacks of herbivorous animals, parasitic fungi and bacteria, and excessive heat or cold.

The outermost layer of the root is called the **epiblema** or **piliferous layer**. It is mainly concerned with the absorption of water and mineral salts from the soil. Thus to increase the absorbing surface which may be 5 to 20 times greater, the outer walls of most of its cells a little behind the apex (see fig. 41) extend outwards and form tubular unicellular root-hairs. The epiblema is neither cutinized nor is it provided with stomata.

Stomata. Structure and Behaviour. **Stomata** (*stoma*, a mouth) are very minute openings (fig. 297) formed in the epidermal layer in green aerial parts of the plant, particularly the leaves. Roots and non-green parts of the stem are free from them. Each stoma is surrounded by two semi-lunar cells, known as the *guard cells*. The term 'stoma' is often applied to the stomatal opening plus the guard cells. The guard cells are living and always contain chloroplasts, and their inner walls are thicker and outer walls thinner. They guard the stoma or the passage, i.e. they regulate the opening and closing of it like lips. Under normal conditions the stomata remain closed

FIG. 297.
Stomata
in epidermal
layer (surface
view).

at night, i.e. in the absence of light, and they remain open during the daytime, i.e. in the presence of light. They may close up at daytime when very active transpiration (evaporation of water) takes place from the surface of the leaf under certain conditions such as high temperature, dryness of the air, blowing of dry wind and deficient supply of water in the soil. The opening and closing of the stomata are due to the movement of the guard cells, and this movement is mainly connected with two factors—light and water. In the presence of light the guard cells absorb water from the neighbouring cells, expand and bulge in an outward direction and the

stoma opens. In the absence of light the guard cells lose water and become flaccid and the stoma closes. The intensity of light also directly affects the degree of stomatal opening.

The expansion or contraction of the guard cells is due to the presence of sugar or starch in them. In light the sugar manufactured by the chloroplasts of the guard cells accumulates in them, and being soluble, increases the concentration of the cell-sap. Under this condition the guard cells absorb water from the neighbouring cells and become turgid, and the stoma opens. In darkness on the other hand the sugar present in the guard cells becomes converted into starch—an insoluble compound. The concentration of the cell-sap is, therefore, lower than that of the neighbouring cells. Under this condition the guard cells lose water and shrink, and the stoma closes.

Functions and Distribution. Stomata are used for interchange of gases between the plant and the atmosphere—oxygen for respiration and carbon dioxide for manufacture of carbohydrates. For the facility of diffusion of these gases each

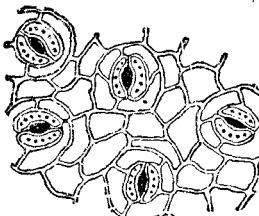

FIG. 298

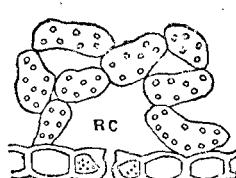

FIG. 299

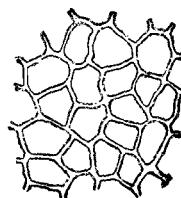

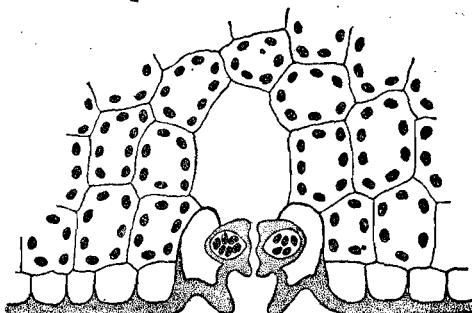

FIG. 300

Stomata in betel leaf. FIG. 298. Lower epidermis with numerous stomata. FIG. 299. Section of leaf (a portion of the lower side); *RC*, respiratory cavity internal to a stoma. FIG. 300. Upper epidermis with no stoma.

stoma opens internally into a small cavity, known as the **respiratory cavity** (fig. 299) which in its turn communicates with the system of intercellular spaces and air-cavities. Stomata are also the organs through which evaporation of water takes place; in this way the plant gets rid of the surplus water. Stomata are most abundant in the lower epidermis (fig. 298) of the

FIG. 301A. Sunken stomata in the leaf of American aloe (*Agave*).

dorsiventral leaf (see p. 51); none (or sometimes comparatively few) are present in the upper (fig. 300). In the isobilateral leaf stomata are more or less evenly distributed on all sides (see fig. 313). In the floating leaves, as in those of the water lily, stomata remain confined to the upper epidermis alone; in the submerged leaves no stoma is present. In plants growing in deserts or dry regions, e.g. American aloe (fig. 301A), oleander (fig. 301B), etc., stomata occur sunken in pits to reduce excessive transpiration against gusts of wind.

The number of stomata per unit area varies within wide limits. In ordinary land plants there is an average of about 100 to 300 stomata per square millimetre, sometimes much less or many more. In desert plants they may be only 10 to 15 in the same area.

2. The Ground or Fundamental Tissue System. This system forms the main bulk of the body of the plant, and extends from below the epidermis to the centre (excluding the vascular bundles). This system consists of various kinds of tissues, of which parenchyma is the most abundant. It is differentiated into the following zones and sub-zones.

(1) **Cortex.** This is the zone that lies between the epidermis and the pericycle, varying in thickness from a few to many layers. In dicotyledonous stems (see fig. 304) it is usually differentiated into the following sub-zones: (a) **hypodermis**—a few external layers of collenchyma or sometimes sclerenchyma; (b) **general cortex** or cortical parenchyma—a few middle layers of thin-walled cells with or without chloroplasts; and (c) **endodermis**—a single internal layer, often wavy; it is also called *starch sheath* as it often contains numerous starch grains. In monocotyledonous stems (see fig. 306), owing to the scattered arrangement of vascular bundles, there is no such differentiation into sub-zones. In roots (see fig. 309) the cortex

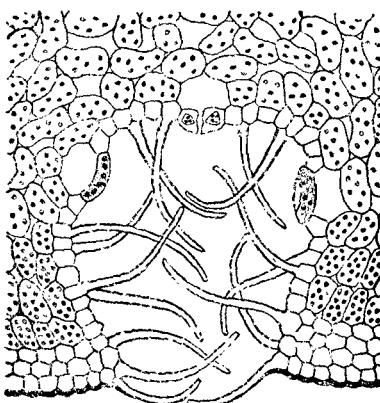

FIG. 301B. Sunken stomata in the leaf of oleander (*Nerium*).

consists of (*a*) many layers of thin-walled parenchyma and (*b*) a distinct circular layer of endodermis.

Functions. In stems the cortex primarily functions as a protective tissue ; its secondary functions are the manufacture and storage of food. In roots the cortex is essentially a storage tissue. It is also the pumping station of the root where the individual cells by their alternate expansion and contraction act as pumps forcing water, absorbed by the root-hairs, into the xylem vessels.

(2) **Pericycle.** This forms a multi-layered zone between the endodermis and the vascular bundles and occurs as a cylinder encircling the vascular bundles and the pith, as in dicotyledonous stems. It may consist wholly of sclerenchyma forming a continuous zone, as in the gourd stem (see fig. 305), but more commonly it is made of both parenchyma and sclerenchyma, the latter forming isolated strands in it. Each such strand associated with the phloem or bast of the vascular bundle in the form of a cap is known as the **hard bast**, as in the sunflower stem (see fig. 304). In roots the pericycle consists of a single layer of small, very thin-walled, more or less barrel-shaped cells.

Functions. In all roots the pericycle is the seat of origin of lateral roots (see fig. 311). In dicotyledonous roots it further gives rise to lateral meristems—a portion of the cambium (see fig. 318) and later the whole of the cork cambium (see fig. 320). In all stems the pericycle is the seat of origin of adventitious roots. Otherwise its function is mechanical or storage.

(3) **Pith and Pith Rays.** The **pith** or **medulla** forms the central core of the stem and the root and is usually made of large-celled parenchyma with abundant intercellular spaces. In the dicotyledonous stem the pith is often large and well developed. In the dicotyledonous root the pith is either small or absent, bigger vessels having met in the centre ; while in the monocotyledonous root a distinct large pith is present. It is often parenchymatous, but sometimes sclerenchymatous. In the dicotyledonous stem the pith extends outwards to the pericycle between the vascular bundles. Each such extension, which is a strip of parenchyma, is called the **pith ray** or **medullary ray**. It is not present as such in the root.

Functions. They serve to store food material. The function of the sclerenchymatous pith is, of course, mechanical. The medullary ray further transmits water and food material

outwards to the peripheral tissues, and is the seat of origin of a strip of cambium (see fig. 314) prior to secondary growth.

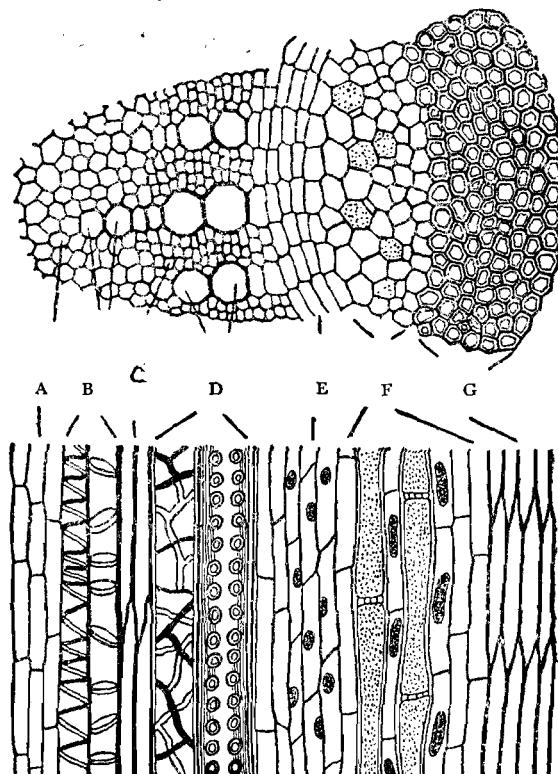

3. The Vascular Tissue System. This system consists of a number of vascular bundles which are distributed in the **stele**. The stele is the central column of the dicotyledonous stems and all roots surrounded by the endodermis and consists of pericycle, vascular bundles, medullary rays and pith. Each bundle may be made up of both **xylem tissue** and **phloem tissue** with a cambium, as in dicotyledonous stem, or without a cambium, as in monocotyledonous stems, or of only one kind of tissue—xylem or phloem, as in roots. The function of this system is to conduct water and raw food materials from the roots to the leaves, and prepared food materials from the leaves to the storage organs and the growing regions. The vascular bundles may be regularly arranged in a ring, as in the stems of most dicotyledons and in all roots, or they may be scattered in the ground tissue, as in the stems of monocotyledons.

Elements of a Vascular Bundle (fig. 302). A vascular bundle of a dicotyledonous stem, when fully formed, consists of three well-defined tissues: (1) xylem or wood, (2) phloem or bast, and (3) cambium. They have different kinds of tissue elements.

(1) **Xylem or Wood** (see pp. 158-60). This lies towards the centre, and is composed of the following elements: (1) tracheae or vessels, (2) some tracheids, (3) a number of wood fibres, and (4) a small patch of wood parenchyma. Vessels are of various kinds (see fig. 289) such as *spiral*, *annular*, *scalariform*, *reticulate* and *pitted* (with simple or bordered pits). Some tracheids also lie associated with the vessels. Wood fibres and wood parenchyma are ordinary sclerenchymatous and parenchymatous cells lying associated with the wood or xylem, and provided with simple pits in their walls. Xylem vessels and tracheids are used for the *conduction* of water and mineral salts from the roots to the leaves and other parts of the plant; xylem parenchyma assists them in their task and also serves for food storage, and wood fibres give proper rigidity to the xylem. Except for the wood parenchyma all the other elements of xylem are dead and lignified, and hence their secondary function is to give mechanical strength to the plant. The first-formed xylem or **protoxylem** consists of *annular*, *spiral* and *scalariform* vessels; it lies towards the centre of the stem

and its vessels have smaller cavities. The later-formed xylem or **metaxylem** consists of *reticulate* and *pitted* vessels and some *tracheids*; it lies away from the centre and its vessels

have much bigger cavities. The development of xylem is *centrifugal* in the stem.

(2) **Phloem** or **Bast** (see pp. 160-62). This lies towards the circumference, and consists of (1) sieve tubes, (2) companion cells, and (3) phloem parenchyma. Companion cells and phloem parenchyma are provided with simple pits, particularly in the walls lying against the sieve-tubes. Phloem as a whole is used for translocation of prepared food materials from the leaves to the storage organs and also to the different growing regions. All the elements of phloem are made of cellulose, and are living. Primary phloem hardly ever contains bast fibres but it may be capped by a patch of sclerenchyma, called *hard bast*, as seen in the sunflower stem (see fig. 304). The outer portion of phloem consisting of narrow sieve-tubes is the

first-formed phloem or **protophloem**, and the inner portion consisting of bigger sieve-tubes is the later-formed phloem or **metaphloem**.

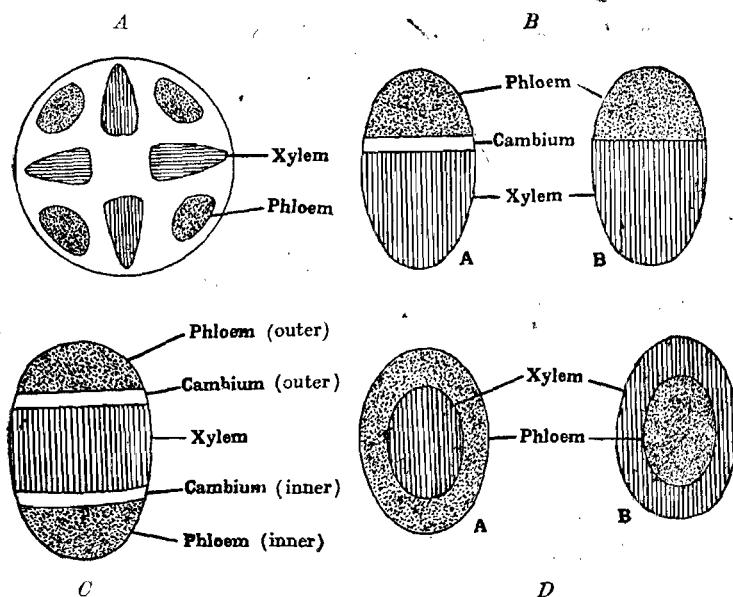

(3) **Cambium**. This is a thin strip of primary meristem lying in between xylem and phloem. It usually consists of a few layers of thin-walled and roughly rectangular cells. Although cambial cells look rectangular in transverse section, they are much elongated, often with oblique ends. They become flattened tangentially, i.e. at right angles to the radius of the stem.

Types of Vascular Bundles (fig. 303). According to the arrangement of xylem and phloem, the vascular bundles are of the following types.

(1) **Radial** (A), when xylem and phloem form separate bundles and these lie on different radii alternating with each other, as in roots.

(2) **Conjoint**, when xylem and phloem combine into one bundle. There are different types of conjoint bundles.

(a) **Collateral** (B), when xylem and phloem lie together on the same radius, xylem being internal and phloem external. When in a collateral bundle the cambium is present, as in

Types of Vascular Bundles. FIG. 303. A, radial; B, collateral—A, open; B, closed; C, bicollateral; D, concentric—A, xylem central; B, phloem central.

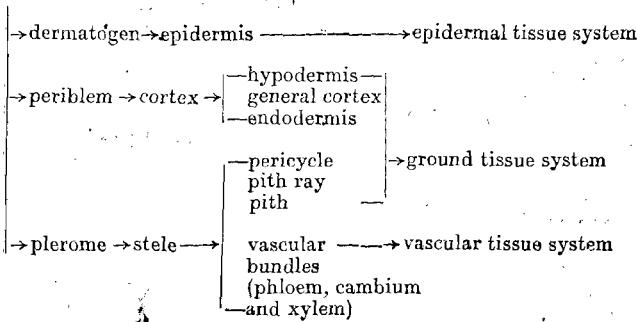

dicotyledonous stems, the bundle is said to be *open*, and when the cambium is absent it is said to be *closed*, as in monocotyledonous stems.

(b) **Bicollateral** (C), when in a collateral bundle both phloem and cambium occur twice—once on the outer side of the xylem and then again on its inner side. The sequence is: outer phloem, outer cambium, xylem, inner cambium and inner phloem. Bicollateral bundle is characteristic of the gourd family. It is always open.

(c) **Concentric** (D), when xylem lies in the centre and is surrounded by phloem, as in ferns, or phloem lies in the centre and is surrounded by xylem; the latter is found only in some monocotyledons, e.g. sweet flag (*Acorus*; B. & H. boch), dragon plant (*Dracaena*) and dagger plant (*Yucca*). A concentric bundle is always closed.

Apical Meristems and Tissue Systems

PROMERISTEM

CHAPTER 4 Anatomy of Stems

DICOTYLEDONOUS STEMS

- Young Sunflower Stem** (fig. 304). Prepare a thin transverse section of the stem and properly stain it with safranin. All the lignified elements are stained deep red. At first note under a pocket lens the distribution of three zones in it: epidermis, cortex and stele; in the stele note the distribution of numerous vascular bundles in a ring and also a large pith. Then under a microscope study the internal structure of a sector in detail.

(1) **Epidermis.** This forms the outermost layer, and consists of a single row of cells, flattened tangentially and fitting closely

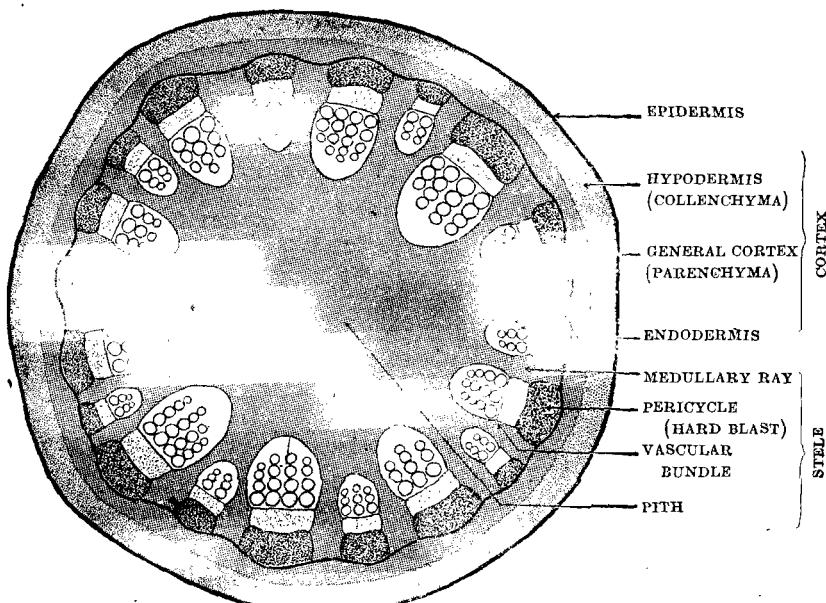

FIG. 304A. Young sunflower stem in transection, as seen under a pocket lens.

along their radial walls, with a well-defined cuticle extending over it. Here and there it bears some multicellular hairs and a few stomata, but no chloroplasts except in the guard cells.

(2) **Cortex.** This is the zone that lies in between the epidermis and the pericycle, and consists of hypodermis externally, general cortex centrally, and endodermis internally.

(a) **Hypodermis (collenchyma)**—this lies immediately below the epidermis, and consists of some 4 or 5 layers of collenchymatous cells. These cells are specially thickened at the corners against the intercellular spaces owing to a deposit of cellulose and pectin. The cells are living and contain a number of chloroplasts. (b) **General cortex**—this lies internal to the hypodermis and consists of a few layers of thin-walled, large, rounded or oval, parenchymatous cells. It may be reduced to 1 or 2 layers outside the vascular bundle. There are conspicuous intercellular spaces in it. Some isolated resin ducts are also seen here and there in it. (c) **Endodermis**—this is the innermost layer of the cortex consisting of more or less barrel-shaped cells and surrounding the stele. Endodermis is con-

spicuous outside the hard bast, but often loses its identity on either side. It contains numerous starch grains and is also known as the **starch sheath**.

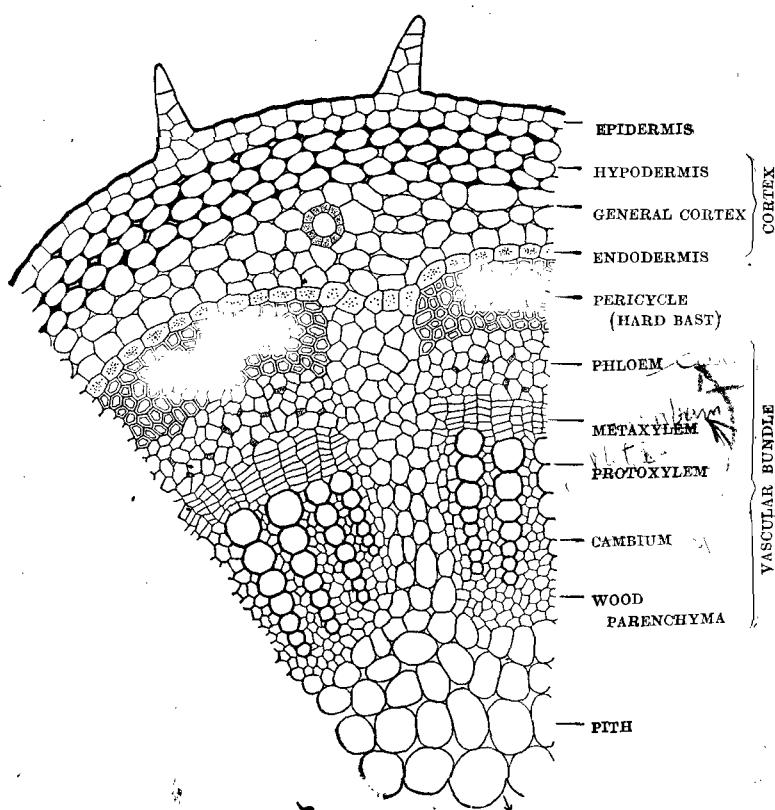

FIG. 304B. Young sunflower stem (a sector) in transection.

(3) **Pericycle.** This is the region lying in between the endodermis and the vascular bundles, and is represented by semi-lunar patches of sclerenchyma and the intervening masses of parenchyma. Each patch associated with the phloem of the vascular bundle is called the **hard bast**.

(4) **Medullary Rays.** A few layers of fairly big polygonal or radially elongated cells, lying in between two vascular bundles, constitute a medullary ray.

(5) **Pith.** This is very large in the sunflower stem, and occupies the major portion of it. It extends from below the vascular bundles to the centre, and is composed of rounded or

polygonal, thin-walled, living cells with conspicuous inter-cellular spaces between them.

(6) **Vascular Bundles.** These are collateral and open, and are arranged in a ring. Each bundle is composed of (a) **phloem** or **bast**, (b) **cambium** and (c) **xylem** or **wood**.

(a) **Phloem.** This lies externally and is made of only thin and cellulose-walled elements. It consists of (i) **sieve-tubes**, which are the larger elements; (ii) **companion cells**, which are the smaller cells associated with the sieve-tubes; and (iii) **phloem parenchyma**, which is the remaining mass of small cells. All the above phloem elements are living, and contain various kinds of food material.

(b) **Cambium.** Passing inwards, a band of thin-walled tissue is seen, lying in between the phloem and xylem; this is the cambium. Its cells are arranged in radial rows and are roughly rectangular in shape, very small in size and very thin-walled.

(c) **Xylem or Wood.** This lies internally and consists of the following elements. (i) **Wood vessels** are the large, lignified, thick-walled elements distributed in a few radial rows. The smaller vessels lying towards the centre constitute the *protoxylem*, and the bigger ones lying away from the centre constitute the *metaxylem*. Protoxylem consists of annular, spiral and scalariform vessels, and metaxylem of reticulate, and pitted vessels. (ii) **Tracheids** and (iii) **wood fibres** are the smaller thick-walled and lignified cells lying around the metaxylem vessels and in between them. In transverse section of the stem these two can hardly be distinguished from each other. (iv) **Wood Parenchyma** is the patch of thin-walled parenchyma lying on the inner side of the bundle surrounding the protoxylem. Its cells are living.

2. **Young Gourd (*Cucurbita*) Stem** (fig. 305). Prepare a thin transverse section of the stem and stain it properly with safranin. Note under a pocket lens the three zones in it—epidermis, cortex and stele. Further note the five ridges and five furrows, ten vascular bundles in two rows, the outer row corresponding to the ridges and the inner row to the furrows, and the central cavity (the stem being hollow). Then under a microscope study the internal structure of a sector in detail.

(1) **Epidermis.** This is the single outermost layer passing

over the ridges and furrows; it often bears many long and narrow multicellular hairs.

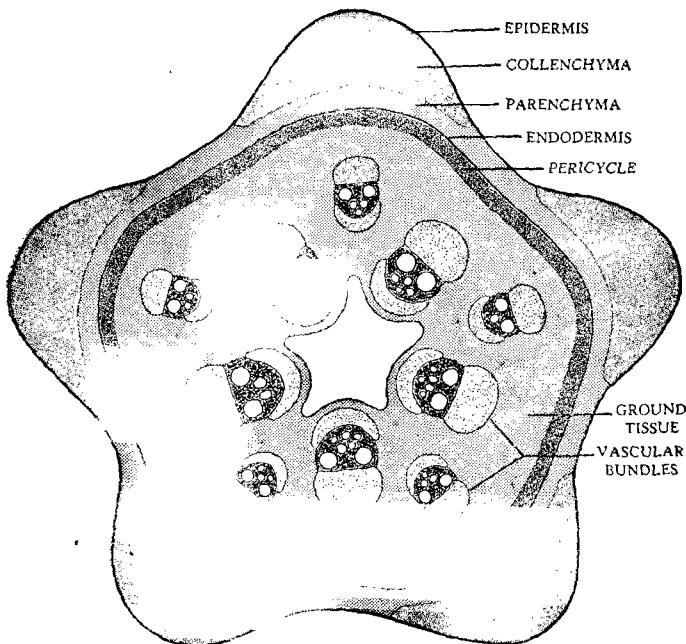

FIG. 305A. Young gourd (*Cucurbita*) stem in transection, as seen under a pocket lens.

(2) **Cortex.** This consists of hypodermis externally, general cortex in the middle, and endodermis internally. (a) **Hypodermis** (collenchyma) lies immediately below the epidermis, and consists of six or seven (sometimes more) layers of collenchymatous cells in the ridges. In the furrows the number of layers is reduced to two or three, sometimes none; in the furrows the underlying parenchyma may be seen to pass right up to the epidermis. Collenchyma contains some chloroplasts. (b) **General cortex** forms a narrow zone of parenchyma, two or three layers thick. In the furrows it often passes outwards right up to the epidermis. Chloroplasts are abundant in the cortex. (c) **Endodermis** is the innermost layer of the cortex, lying immediately outside the pericycle. This layer is wavy in outline and contains starch grains.

(3) **Pericycle.** Below the endodermis there is a zone of sclerenchyma which represents the pericycle. This zone consists of four or five layers of thick-walled, lignified cells which are polygonal in shape.

(4) **Ground Tissue.** This is the continuous mass of thin-walled parenchyma extending from below the sclerenchyma to the pith cavity; in this tissue lie embedded the vascular bundles.

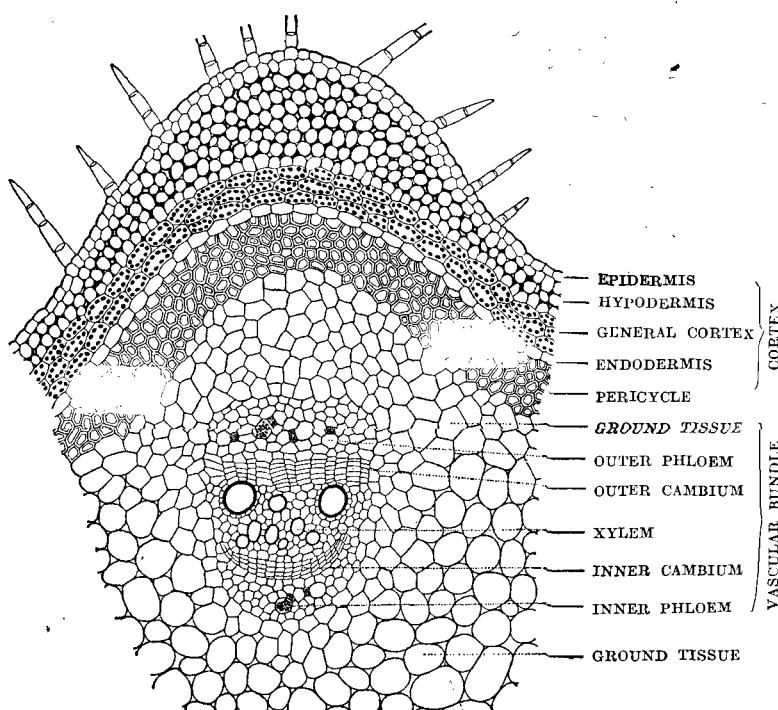

FIG. 305B. Young gourd (*Cucurbita*) stem (a sector) in transection.

(5) **Vascular Bundles.** These are *bicollateral*, usually ten in number, and are arranged in two rows. Each bundle consists of (a) **xylem**, (b) **two strips of cambium**, and (c) **two patches of phloem**.

(a) **Xylem** occupies the centre of the bundle, and consists, on the outer side, of very wide vessels (pitted) which constitute the *metaxylem*, and on the inner side, of narrower vessels which constitute the *protoxylem*. Protoxylem vessels remain scattered. There may be some tracheids and wood fibres, but wood parenchyma is abundant.

(b) **Cambium.** This tissue occurs in two strips—the outer and the inner—one on each side of xylem. Its cells are thin-walled and rectangular, and arranged in radial rows. The

outer cambium is many-layered and is more or less flat, while the inner cambium is few-layered and curved. Each strip of cambium gradually merges into phloem and xylem.

(c) **Phloem** occurs in two patches—the outer and the inner. Note that the outer phloem is plano-convex and the inner one semi-lunar in shape. Each patch of phloem consists of sieve-tubes, companion cells, and phloem parenchyma. Sieve-tubes are very conspicuous in the phloem of the *Cucurbita* stem. Here and there sieve-plates with perforations in them may be distinctly seen. The rest of the phloem is made up of small, thin-walled cells which constitute the phloem parenchyma.

MONOCOTYLEDONOUS STEMS

1. **Indian Corn or Maize Stem** (fig. 306). Cut a thin transverse section and properly stain it with safranin. Note under

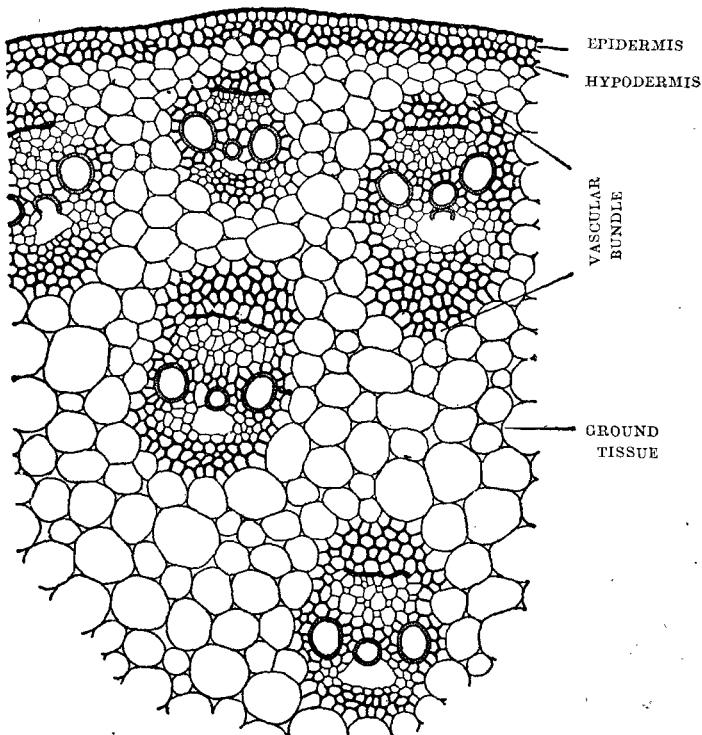

FIG. 306. Maize or Indian corn stem (a sector) in transection.
the microscope the internal structure in detail from the circumference to the centre.

(1) **Epidermis.** This is a single outermost layer with a thick cuticle on the outer surface. Here and there in the epidermis a few stomata may be seen.

(2) **Hypodermis** (sclerenchyma). This forms a narrow zone of sclerenchyma, usually two or three layers thick, lying below the epidermis.

(3) **Ground Tissue.** This is the continuous mass of thin-walled parenchyma, extending from below the sclerenchyma to the centre. It is not differentiated into cortex, endodermis, pericycle, etc., as in a dicotyledonous stem. The cells of the ground tissue enclose numerous intercellular spaces.

(4) **Vascular Bundles** (fig. 307). These are collateral and closed, and lie scattered in the ground tissue; they are more numerous, and lie closer together nearer the periphery than

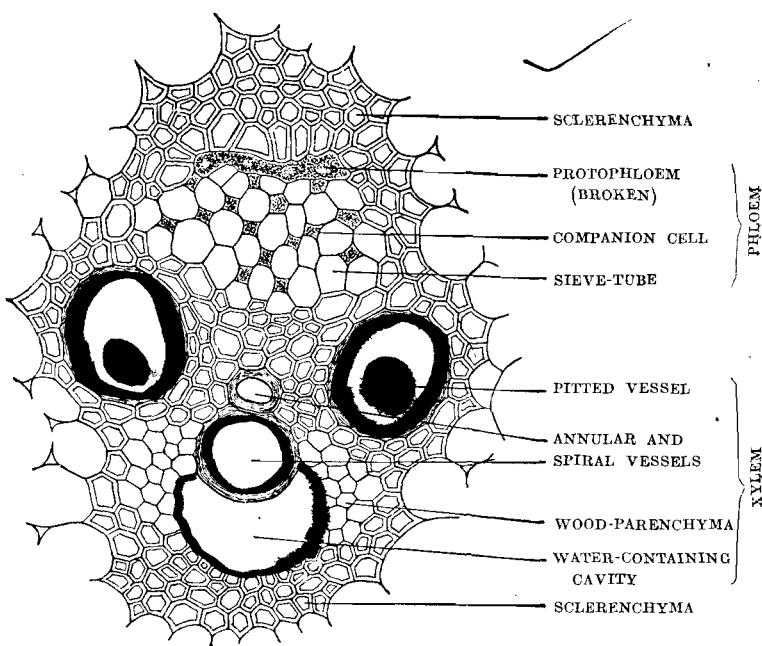

FIG. 307. A vascular bundle of maize stem (magnified).

the centre. The peripheral ones are also seen to be smaller in size than the central ones. Each vascular bundle is somewhat oval in general outline and is more or less completely surrounded by a **sheath** of sclerenchyma which is specially developed on the two sides—upper and lower. The bundle consists

of (a) xylem and (b) phloem only; cambium is altogether absent.

(a) **Xylem** consists mainly of usually four distinct vessels arranged in the form of a Y, and a small number of tracheids arranged irregularly. The two smaller vessels (annular and spiral) lying radially towards the centre constitute the *protoxylem*, and the two bigger vessels (pitted) lying laterally together with the small pitted tracheids lying in between them constitute the *metaxylem*. Besides, thin-walled wood (or xylem) parenchyma almost surrounding a conspicuous water-containing cavity is present in the protoxylem, and a few wood fibres occur associated with the tracheids in between the two big pitted vessels. The said water-containing cavity has been formed lysigenously, i.e. by the breaking down of the inner protoxylem vessel and the contiguous parenchyma during the rapid growth of the stem.

(b) **Phloem** consists exclusively of sieve-tubes and companion cells; no phloem parenchyma is present in the monocotyledonous stem. The outermost portion of the phloem, which is a broken mass, is the *protophloem*, and the inner portion is the *metaphloem*. The former soon gets disorganized, and the latter shows distinct sieve-tubes and companion cells.

Differences between Dicotyledonous and Monocotyledonous Stems

	Dicotyledonous stem (e.g. sunflower)	Monocotyledonous stem (e.g. maize)
1. Hypodermis	collenchymatous	sclerenchymatous.
2. General Cortex	a few layers of parenchyma	a continuous mass of parenchyma up to the
3. Endodermis	a wavy layer	centre (ground tissue)
4. Pericycle	a zone of parenchyma and sclerenchyma	without differentiation into distinct tissues.
5. Medullary Ray	a strip of parenchyma in between vascular bundles	not marked out.
6. Pith	the central cylinder	not marked out.
7. Vascular Bundles	(a) collateral and open (b) arranged in a ring (c) of uniform size (d) phloem parenchyma present (e) usually wedge-shaped (f) bundle sheath absent	collateral and closed. scattered. larger towards the centre. it is absent. usually oval. strongly developed.

2. **Flowering Stem (Scape) of Canna** (fig. 308). A thin transverse section stained with safranin shows clearly the following internal structure under a microscope.

(1) **Epidermis.** This is the single outermost layer of very small, polygonal cells flattened tangentially. Its outer walls are cutinized.

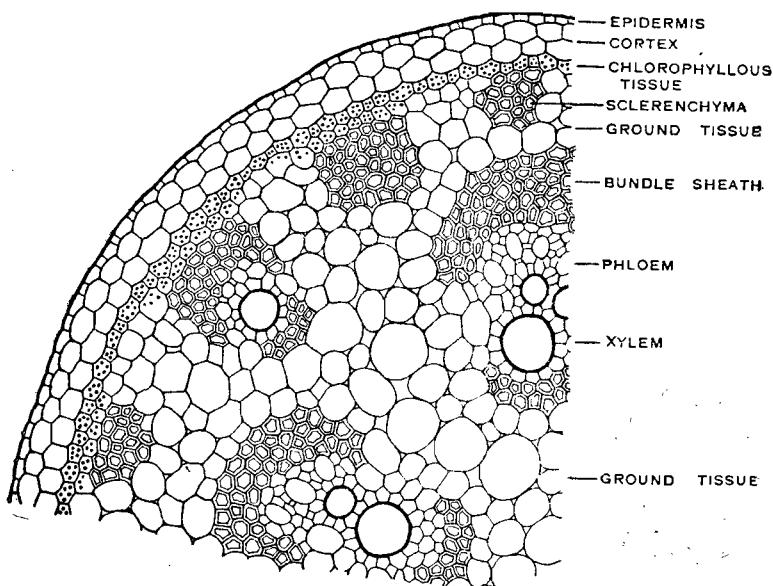

FIG. 308. Flowering stem (scape) of *Canna* (a sector) in transection.

(2) **Ground Tissue System:** From below the epidermis to the centre the whole mass of tissues, leaving out the vascular bundles, constitutes the ground tissue system. It is differentiated into (a) **cortex**, consisting of two layers of fairly large polygonal cells, (b) **chlorophyllous tissue**, consisting of one or two layers of chloroplast-bearing cells, intruding inwards here and there, (c) several patches of **sclerenchyma** of different sizes, lying against the chlorophyllous tissue, and (d) **ground tissue**, consisting of a continuous mass of large, thin-walled, parenchymatous cells, containing starch grains and enclosing numerous intercellular spaces between them.

(3) **Vascular Bundles.** These are numerous and of different sizes, lying scattered in the ground tissue. Each bundle is collateral and closed. It is incompletely surrounded by a sheath of sclerenchyma (**bundle sheath**), with a distinct patch of it on the outer side in the form of a cap, and a thin strip on the inner side; seldom is a regular and complete sheath

formed encircling the vascular bundle. Each bundle consists of (a) xylem on the inner side, and (b) phloem on the outer. **Xylem** consists of a large prominent spiral vessel, often with one or two smaller ones, also spiral in nature, lying usually on its outer side, and some parenchyma. **Phloem** consists of sieve-tubes and companion cells.

CHAPTER 5 *Anatomy of Roots*

1. **Young Dicotyledonous Root** (fig. 309). A thin transverse section stained with safranin shows under a microscope the following internal structure from the circumference to the centre.

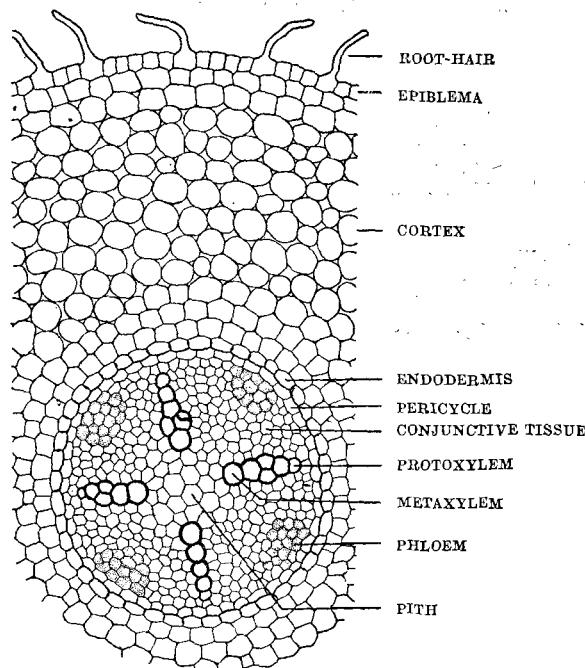

FIG. 309. Young dicotyledonous root in transection.

(1) **Epiblema or Piliferous Layer.** This is a single outermost layer of thin-walled cells; the outer walls of most of these cells extend outwards and form unicellular root-hairs. This layer is used for absorption of water and various mineral salts from the

soil and, therefore, has no cuticle. Root-hairs increase the absorbing surface of the root.

(2) **Cortex.** This consists of many layers of thin-walled rounded cells, with numerous intercellular spaces between them. The cells of the cortex contain leucoplasts and store starch grains.

(3) **Endodermis.** This is a single ring-like layer of barrel-shaped cells which are closely packed without intercellular spaces. The radial walls of this layer are often thickened, and sometimes this thickening extends to the inner walls also. The endodermis is the innermost layer of the cortex and surrounds the stele as a cylinder.

(4) **Pericycle.** This lies internal to the endodermis, and, like it, is a single ring-like layer; its cells, however, are much smaller and thinner-walled, but with abundant protoplasm.

(5) **Conjunctive Tissue.** The parenchyma lying between the xylem and phloem bundles constitutes the *conjunctive tissue*.

(6) **Pith.** This occupies only a small area in the centre of the root. Sometimes the pith is nearly obliterated owing to the wood vessels meeting in the centre.

(7) **Vascular Bundles.** These are arranged in a ring, as in the dicotyledonous stem, but here xylem and phloem form an equal number of separate bundles, and their arrangement is *radial* (see p. 174). The number of xylem or phloem bundles varies from two to six, very seldom more. The cambium is absent in the young root but soon makes its appearance.

Phloem bundle consists of sieve-tubes, companion cells and phloem parenchyma. **Xylem bundle** consists of protoxylem which lies towards the circumference abutting on the pericycle, and metaxylem towards the centre. The development of xylem is *centripetal*. Protoxylem is composed of small vessels (annular and spiral) and metaxylem of bigger vessels (reticulate and pitted). The metaxylem groups often meet in the centre, and then the pith gets broken.

2. **Monocotyledonous Root** (fig. 310). A thin transverse section stained with safranin reveals the following internal structure under a microscope.

(1) **Epiblema or Piliferous Layer.** This is the single outermost layer with a number of unicellular root-hairs.

(2) **Cortex.** This is a many-layered zone of rounded or oval cells with intercellular spaces between them.

(3) **Endodermis.** This is the innermost layer of the cortex

and forms a definite ring around the stele. Radial walls and often the inner walls of the endodermis are considerably thickened. Cells of the endodermis are barrel-shaped.

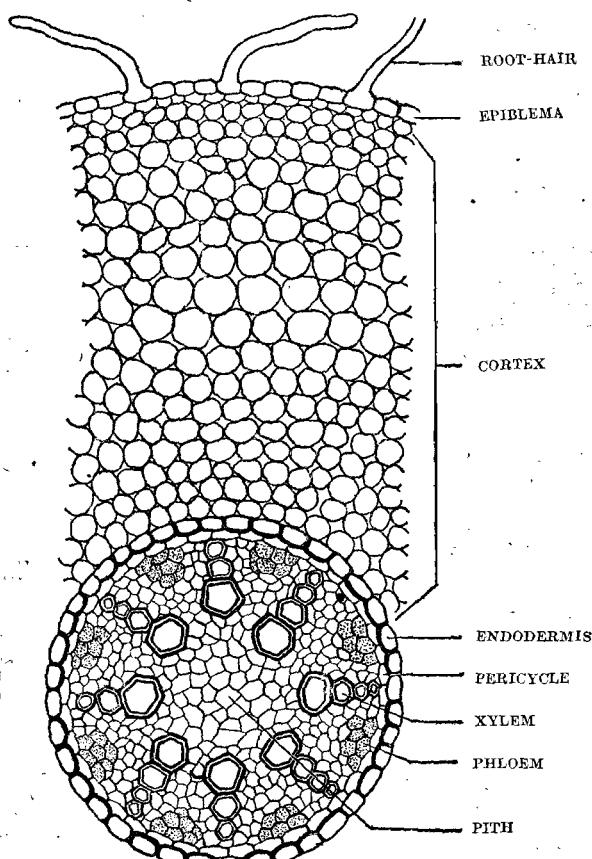

FIG. 310. Monocotyledonous root in transection.

(4) **Pericycle.** This is the ring-like layer lying internal to the endodermis. Its cells are very small and thin-walled, but contain abundant protoplasm.

(5) **Conjunctive Tissue.** The parenchyma in between the xylem and phloem bundles is known as the *conjunctive tissue*.

(6) **Pith.** The parenchymatous mass of cells in the central portion of the root is the pith. It is well developed in most monocotyledonous roots. In some cases the pith becomes thick-walled and lignified.

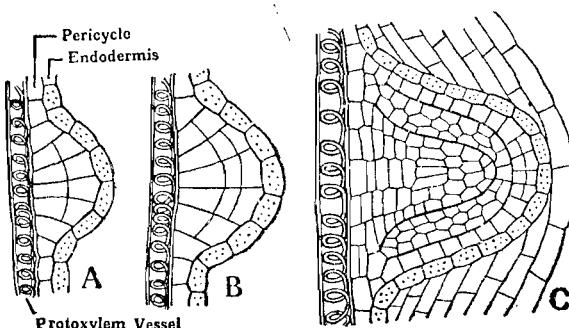

(7) **Vascular Bundles.** Xylem and phloem form an equal number of separate bundles, and they are arranged in a ring. The arrangement is *radial* (see p. 174). Bundles are numerous. It is only in exceptional cases that they are limited in number. **Phloem bundle** consists of sieve-tubes, companion cells and phloem parenchyma. **Xylem bundle** consists of protoxylem which lies abutting on the pericycle, and metaxylem towards the centre. The development of xylem is *centripetal*. Protoxylem consists of annular and spiral vessels, and metaxylem of reticulate and pitted vessels.

Differences between Dicotyledonous and Monocotyledonous Roots

	Dicotyledonous root	Monocotyledonous root
1. Xylem bundles	vary from 2 to 6, rarely more	numerous, rarely a limited number.
2. Pith	small or absent	large and well developed.
3. Pericycle	gives rise to lateral roots, cambium and cork-cambium	gives rise to lateral roots only.
4. Cambium	appears later	altogether absent.

Origin of Lateral Roots (fig. 311). Lateral roots originate from an inner layer; so they are said to be *endogenous*. The inner layer is the pericycle. The cells of the pericycle lying against the protoxylem begin to divide tangentially, and a few layers

FIG. 311.
Origin of a
lateral root.
A, *B*, and *C*
are stages in
its formation
from the pericycle.

are thus cut off. They push the endodermis outwards and tend to grow through the cortex. At this stage the three regions of the root-apex, namely, dermatogen (or calyptrogen), periblem and plerome, become well marked out. The endodermis and some of the cells of the cortex form a part of the root-cap, but as the root passes through the soil this portion soon wears off, and the root-cap is renewed by the calyptrogen.

CHAPTER 6 Anatomy of Leaves

1. **Dorsiventral Leaf** (fig. 312). A dorsiventral leaf (see p. 51) is more strongly illuminated on the upper surface than on the

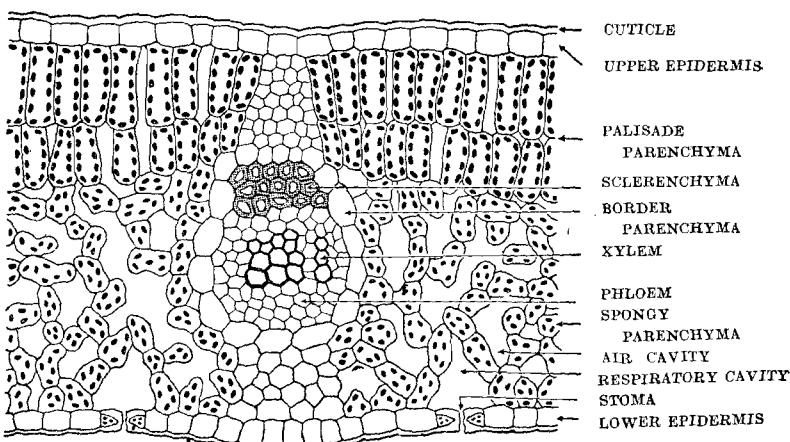

FIG. 312. A dorsiventral leaf in section.

lower. This unequal illumination induces a difference in the internal structure between the upper and the lower sides. A section made at a right angle to one of the bigger veins reveals the following internal structure.

(1) **Upper Epidermis.** This is a single layer of cells with a thick cuticle which checks excessive evaporation of water from the surface. It does not contain chloroplasts. Stomata are also usually absent.

(2) **Lower Epidermis.** This is also a single layer but with a thin cuticle. It is, however, interspersed with numerous stomata, the two guard cells of which contain some chloroplasts; none are present in the epidermal cells. Internal to each stoma a large cavity, known as the *respiratory cavity*, may be seen. The lower epidermis of the leaf is meant for the exchange of gases (oxygen and carbon dioxide) between the atmosphere and the plant body. Excess water also evaporates from the plant body mainly through the lower epidermis.

(3) **Mesophyll.** The ground tissue lying between the upper epidermis and the lower one is known as the mesophyll. It is

differentiated into (a) palisade parenchyma and (b) spongy parenchyma.

(a) **Palisade parenchyma** consists of usually one to two or three layers of elongated, more or less cylindrical cells, closely packed with their long axes at right angles to the epidermis. The cells contain numerous chloroplasts and manufacture sugar and starch in the presence of sunlight.

(b) **Spongy parenchyma** consists of oval, rounded, or more commonly irregular cells, loosely arranged towards the lower epidermis, enclosing numerous, large, intercellular spaces and air-cavities. They, however, fit closely around the vein or the vascular bundle. The cells contain a few chloroplasts. Spongy cells help diffusion of gases through the empty spaces left between them ; they manufacture sugar and starch to some extent only.

(4) **Vascular Bundles.** Each vascular bundle (vein) consists of xylem towards the upper epidermis and phloem towards the lower. **Xylem** consists of various kinds of vessels (particularly annular and spiral), tracheids, wood fibres and wood parenchyma. Xylem conducts and distributes the water and the raw food material to different parts of the leaf-blade. **Phloem** consists of some narrow sieve-tubes, companion cells and phloem parenchyma. Phloem carries the prepared food material from the leaf-blade to the growing and storage regions.

Surrounding each vascular bundle there is a compact layer of thin-walled cells, containing a few chloroplasts or none at all ; this layer is known as the **border parenchyma** or **bundle sheath**. It may extend radially towards the upper and the lower sides.

Frequently **sclerenchyma** occurs as a *sheath*, complete or incomplete, surrounding a bigger bundle, or as patches associated with xylem and phloem. Otherwise its distribution in the leaf is somewhat irregular.

2. **Isobilateral Leaf** (fig. 313). An isobilateral leaf (see p. 51) is more or less equally illuminated on both sides. A section at a right angle to one or more veins reveals the following internal structure.

The structure is more or less uniform from one surface to the other. The epidermis on either side bears more or less an equal number of stomata, and is also somewhat uniformly thickened and cutinized. The mesophyll is often not differen-

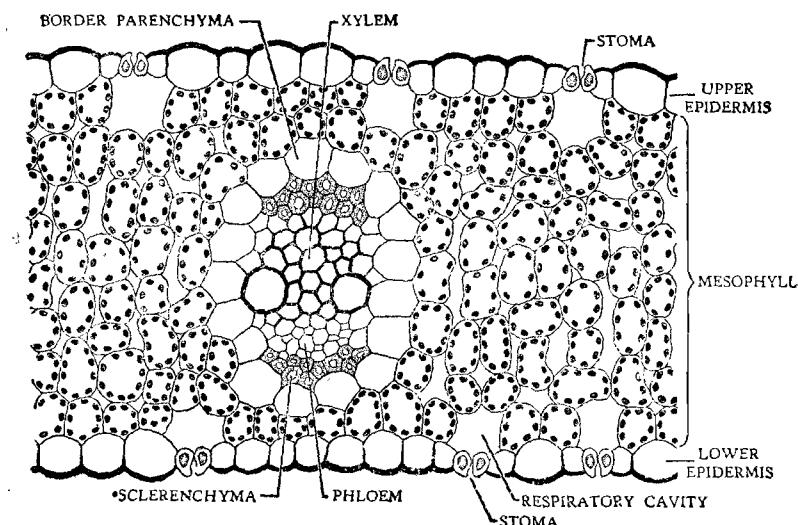

FIG. 313. An isobilateral leaf (a lily leaf) in section.

tiated into palisade and spongy parenchyma, but consists of spongy cells only, in which chloroplasts are evenly distributed.

CHAPTER 7 Secondary Growth in Thickness

1. **Dicotyledonous Stem.** In sturdy herbs and in all shrubs and trees secondary growth takes place as a result of the formation of new (secondary) tissues in them. Secondary tissues are formed by two meristems—**cambium** in the stelar region and **cork-cambium** formed later in the extra-stelar or cortical region. *The increase in thickness due to the addition of secondary tissues cut off by the cambium and the cork-cambium in the stelar and extra-stelar regions respectively is spoken of as secondary growth.*

A. ACTIVITY OF THE CAMBIUM

Cambium Ring. At first a portion of each medullary ray in a line with the cambium becomes meristematic and forms a strip of cambium called the **interfascicular cambium**. This joins on to the cambium proper on either side and forms a complete ring known as the cambium ring (fig. 314). Secondary growth begins with the activity of this cambium ring.

Secondary Tissues. The cambium ring as a whole begins to cut off new cells both externally and internally. Those cut

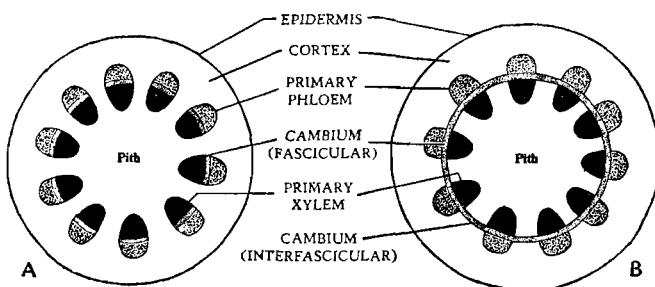

FIG. 314. Formation of cambium ring.

off on the outer side are gradually modified into the elements of phloem ; these constitute the **secondary phloem**. The secondary phloem consists of sieve-tubes, companion cells and phloem parenchyma and often also some bands or patches of bast fibres.

The new cells cut off by the cambium on its inner side are gradually modified into the various elements of xylem ; these constitute the **secondary xylem**. The secondary xylem consists of scalariform and pitted vessels, tracheids, numerous wood fibres arranged mostly in radial rows, and some wood parenchyma. The cambium is always more active on the inner side than on the outer. Consequently xylem increases more rapidly in bulk than phloem, and soon forms a hard compact mass, occupying the major portion of the stem. As xylem increases in bulk the peripheral tissues become stretched and some of them even get crushed. Primary xylem, however, remains intact.

Here and there the cambium forms some narrow bands of parenchyma, radially elongated and passing through the secondary xylem and the secondary phloem ; these are the **secondary medullary rays**. They are one, two or a few layers in thickness, and one to many layers in height. •

Annual Rings (fig. 315). The activity of the cambium increases or decreases according to favourable or unfavourable climatic conditions. Thus it is seen that in spring the cambium becomes more active and forms a greater number of vessels with wider cavities (large pitted vessels) ; while in winter it

becomes less active and forms elements of narrower dimensions (narrow pitted vessels, tracheids and wood fibres). The wood thus formed in the spring is called the **spring wood** or early wood, and that formed in winter is called the **autumn wood** or late wood. These two kinds of wood appear together, in a transverse section of the stem, as a concentric ring known as the **annual ring** or **growth ring**, and successive annual rings are formed year after year by the activity of the cambium. Annual rings are readily seen with the naked eye in the logs of a tree trunk, as in pine and many other timber trees (fig. 315A). Each annual ring corresponds to one year's growth, and therefore, by counting the total number of annual rings the age of the plant can be approximately determined.

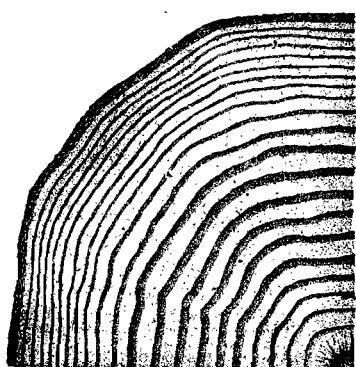

FIG. 315 A. Cut surface of a stem showing annual rings.

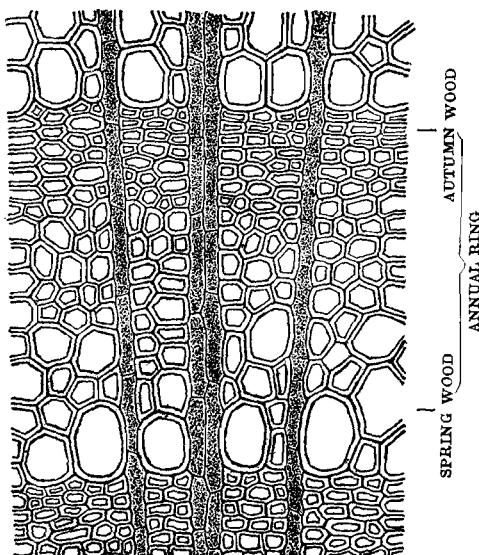

FIG. 315 B. An annual ring in section (magnified).

Heart-wood and **Sap-wood**. In old trees the greater part of the secondary wood is filled up with tannins, resins, gums, essential oils, etc., which make it hard and durable. This region is known as the **heart-wood** or **duramen**. It looks dark or brown. The heart-wood no longer conducts water, but simply gives mechanical support to the stem. The outer region of the secondary wood which is of lighter colour is known as the **sap-wood** or **alburnum**, and this alone is used for conduction of water and salt solutions from the root to the leaf.

B. ORIGIN AND ACTIVITY OF THE CORK-CAMBIUM

Sooner or later another meristematic tissue, i.e. the **cork-cambium** (or phellogen) makes its appearance in the cortical region. Commonly it originates in the outer layer of collenchyma. It may also arise in the epidermis itself, or in the

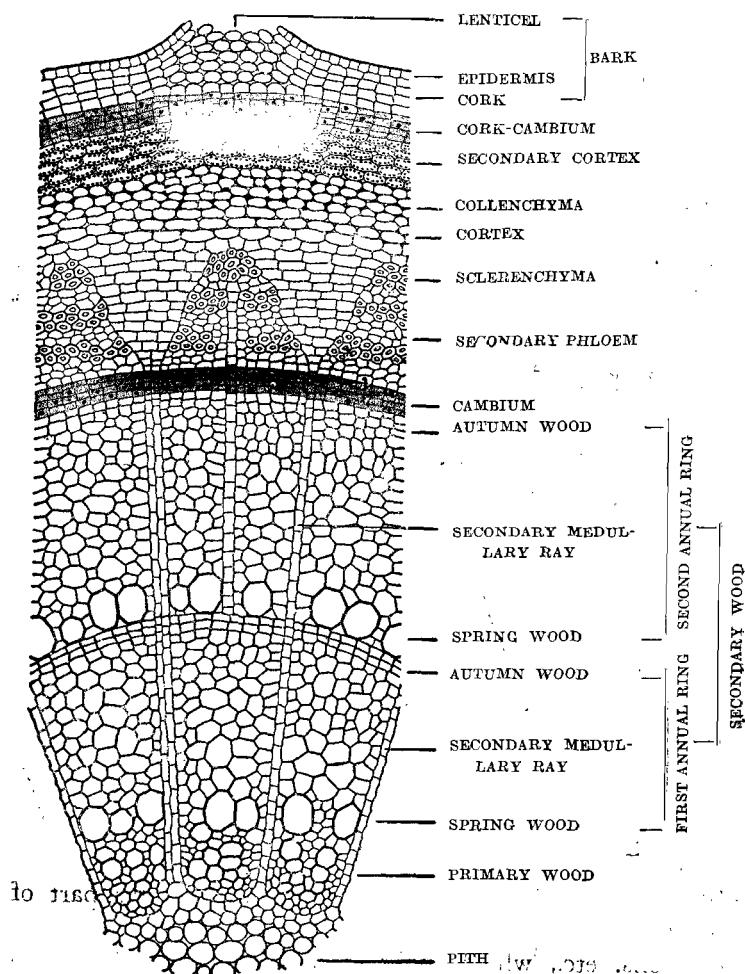

FIG. 316. A two-year old dicotyledonous stem (a sector) in transection showing secondary growth in thickness.

deeper layers of the cortex. It is a few layers in thickness and consists of narrow, thin-walled and roughly rectangular cells. It begins to divide and give off new cells on both sides \rightarrow **cork**

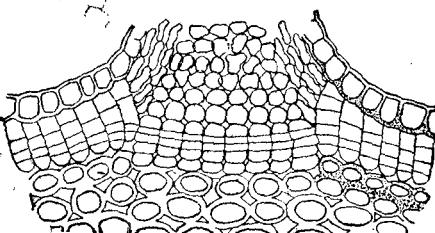

on the outer side and **secondary cortex** on the inner. The cells of the secondary cortex are parenchymatous in nature and often contain chloroplasts.

Cork. The new cells cut off by the cork-cambium on its outer side are roughly rectangular in shape and soon become suberized. They form the **cork** of the plant. Cork cells are dead, suberized and thick-walled, and are arranged in a few radial rows. Cork is usually brownish in colour, and being suberized it is impervious to water. For functions see pp. 198-99.

Bark. All the dead tissues lying outside the active cork-cambium constitute the bark of the plant. It, therefore, includes the epidermis, lenticels and cork, and sometimes also hypodermis and a portion of the cortex, depending on the position of the cork-cambium, that is, the deeper the origin of the cork-cambium, the thicker the bark.

When the cork-cambium appears in the form of a complete ring the bark that is formed comes away in a sheet; such a bark is known as the **ring-bark**, as in *Betula* (B. BHURJAPATRA); and when it appears in strips the resulting bark comes away in the form of scales; such a bark is, therefore, known as the **scale-bark**, as in guava. The function of the bark is to give protection (see p. 199).

Lenticels (fig. 317). These are aerating pores formed in the bark, through which exchange of gases takes place. Externally they appear as scars or small protrusions on the surface of the stem. A section through one of the scars shows that the lenticel consists of a loose mass of small thin-walled cells (complementary cells).

2. **Dicotyledonous Root.** As in the stem the secondary growth in thickness of the root is due to the addition of new tissues cut off by the cambium and the cork-cambium in the interior as well as in the peripheral region. In the root the secondary growth commences a few centimetres behind the apex.

A. ORIGIN AND ACTIVITY OF THE CAMBIUM.

At first the conjunctive tissue on the inner side of phloem becomes meristematic and gives origin to a strip of cambium (fig. 318). The cambium then extends outwards between phloem and xylem. Then the portion of the pericycle just outside the protoxylem becomes meristematic; it divides and forms a strip of cambium there, joining with the earlier-formed cambium strips on either side of the xylem. Thus a continuous wavy band of **cambium** is formed, extending over

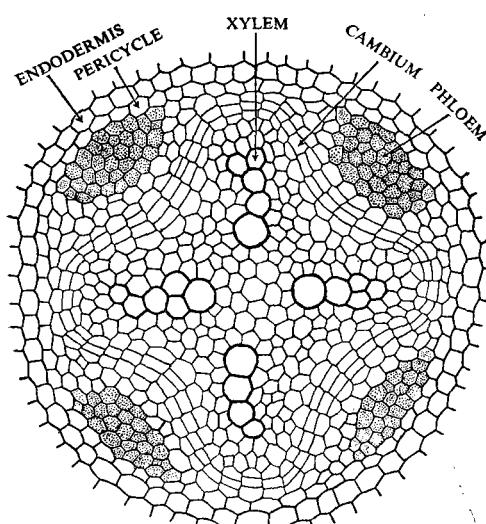

FIG. 318. Secondary growth of a dicotyledonous root (early stage) showing the origin of the cambium.

the xylem and down the phloem. The secondary growth then commences with the activity of this cambium band. The portion of the cambium adjoining the inner phloem becomes active first. It begins to cut off new cells more profusely on the inside. As a result the cambium and the phloem are gradually pushed outwards. The wavy band of cambium soon becomes circular or ring-like (fig.

319). The whole of the cambium ring then becomes active, more so on the inner side than on the outer.

Secondary Xylem. The new cells cut off by the cambium on the inner side gradually become differentiated into the elements of xylem and all these new elements together constitute the secondary xylem. The secondary wood increases rapidly and soon forms the main bulk of the root. It is made of numerous large vessels with comparatively thin walls, abundance of wood parenchyma, but few wood fibres. As more wood is added, the cambium and phloem are gradually pushed further out. As the root lies underground it is not subjected to variations of aerial conditions; consequently

annual rings, which are so characteristic of woody stems, are rarely formed in the root. Even when the root has increased considerably in thickness the primary xylem bundles still remain intact and can be recognized under the microscope in several cases. Against the protoxylem the cambium forms distinct and widening radial bands of parenchyma, which constitute the **medullary rays**. These extend up to the secondary phloem. Other smaller and thinner medullary rays are also formed later by the cambium. Medullary rays are larger and more prominent in the root than in the stem.

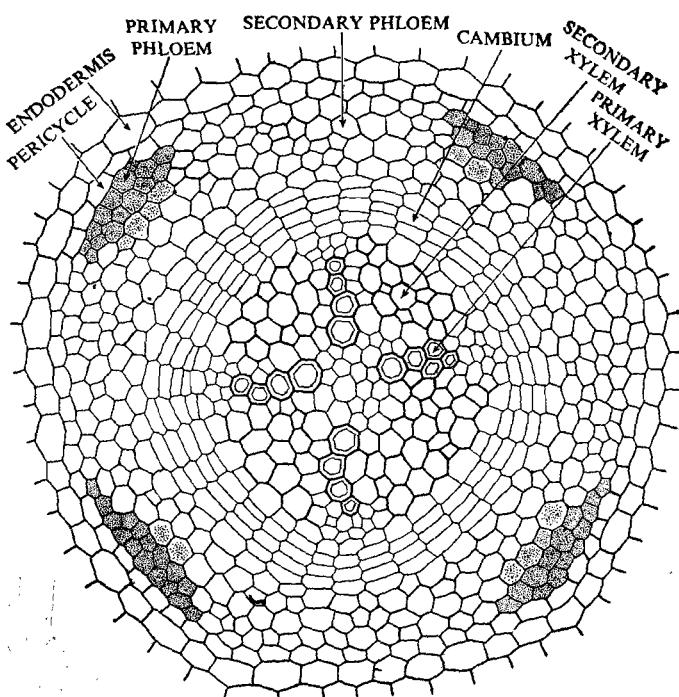

FIG. 319. Secondary growth of a dicotyledonous root (later stage) showing the activity of the cambium with the formation of secondary xylem and secondary phloem.

Secondary Phloem. The new elements cut off by the cambium on the outer side become gradually modified into the elements of phloem, and all these together constitute the secondary phloem. It consists of sieve-tubes with companion cells and abundant parenchyma, but less bast fibres (except in special cases). The secondary phloem is much thinner than the secondary xylem. The primary phloem soon gets crushed.

B. ORIGIN AND ACTIVITY OF THE CORK-CAMBIUM

When the secondary growth has advanced to some extent the single-layered pericycle as a whole becomes meristematic and divides into a few rows of thin-walled, roughly rectangular cells; these constitute the **cork-cambium** or phellogen. As in the stem, it produces a few brownish layers of **cork** on the outside, and the **secondary cortex** on the inside. The secondary cortex of the root does not contain chloroplasts. The **bark** of the root is not extensive; it forms only a thin cover-

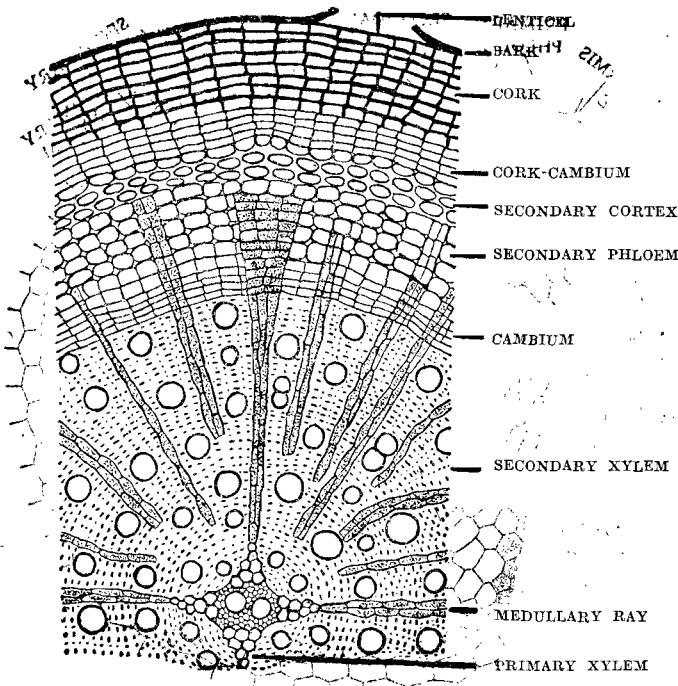

FIG. 320. Secondary growth of dicotyledonous root.

ing. The cortex, being thin-walled, gets disorganized. Such is also the fate of the endodermis. Epiblema dies out earlier. Here and there **lenticels** may be developed, as in the stem.

Functions of Cork and Bark. Cork and bark are protective tissues formed in shrubs and trees. Both are much thicker than the epidermis, but the cork has an additional advantage; it can be renewed by the underlying cork-cambium.

SECONDARY GROWTH IN THICKNESS

(1) **Cork.** (a) All the cork cells are suberized, and thus the cork acts as a waterproof covering to the stem. Loss of water by evaporation is, therefore, prevented or greatly minimized. (b) The cork tissue also protects the plant against the attacks of parasitic fungi and insects. (c) Cork cells, being dead and empty, containing air only, are bad conductors of heat. This being so, a sudden variation in outside temperature does not affect the internal tissues of the plant. (d) Cork is also made use of by the plant for the healing of wounds.

(2) **Bark.** Since bark is a mass of dead tissues lying externally as a hard dry covering, its function is protection. It protects the inner tissues against the attack of fungi and insects, against loss of water by evaporation, and against the variation of external temperature.

PART III PHYSIOLOGY

CHAPTER I *General Considerations*

Physiology deals with the various functions of life, such as the construction of food, nutrition of the protoplasm, building up of the body, respiration, metabolism, reproduction, growth, movements, and so on. All these vital functions are performed by the protoplasm. To maintain the life and activity of the protoplasm the primary requirements are **water, air, food, heat and light.**

Water. Water (see also p. 24) is indispensable to the protoplasm for its manifold activities. There is always a high percentage of water—75·95%—associated with the protoplasm in its active state. Besides, inorganic materials are absorbed from the soil in a state of dilute solution; prepared food travels in the plant through the medium of water; similarly gases reach the protoplasm in solution, and many chemical changes are also carried out in solution in the plant body.

Air. Air is another necessity of the plant. Of the gases present in the air the plant normally utilizes only oxygen and carbon dioxide. The plant requires oxygen for respiration and carbon dioxide for the manufacture of food.

Food. Protoplasm also requires food for its nutrition. This is of primary importance to all living organisms; but unlike animals, plants manufacture their own food from raw food material—water and inorganic salts absorbed from the soil and carbon dioxide absorbed from the air. Food furnishes the necessary materials for body-building and is the source of energy.

Heat. A certain amount of heat is necessary to maintain the activity of the protoplasm and for all the vital processes carried on by it. Within certain limits, the higher the temperature, the greater the activity of the protoplasm. Generally speaking, the maximum temperature may be stated to be 45-50°C., with the optimum lying at about 30°C.

Light. Sunlight is the original source of energy and has a stimulating effect on growth; it makes the plant sturdy. It

is not, however, essential in the early stages of growth. Light is an important factor responsible for green colouration of the plant, utilization of carbon dioxide of the air, and manufacture of sugar and starch. It is also responsible for some kinds of movement in plant organs.

CHAPTER 2 *Soils*

Since water and mineral salts are almost exclusively obtained from the soil for their utilization later in the plant body, a knowledge of soil science in different aspects is an essential prerequisite to the study of plant physiology.

Soil Formation. Soils are formed by the disintegration and decomposition of rocks due to weathering (action of rain-water, running streams, glaciers, wind, alternate high and low temperatures, etc.) and the action of soil organisms such as many bacteria, fungi, protozoa, earthworms, etc., and also interactions of various chemical substances present in the soil. Although soils are normally formed from underlying rocks in a particular region, they may be transported long distances by agencies such as rivers, glaciers, strong winds, etc.

Physical Nature. Physically the soil is a mixture of mineral particles of varying sizes—coarse and fine—of different degrees, some angular and others rounded, with a certain amount of decaying organic matter in it. The soil has been graded into the following types according to the size of the particles:

Coarse particles	... 2-2 mm.	form coarse sand
Smaller particles	... 2-02 mm.	form sand
Finer particles	... 02-002 mm.	form silt
Very fine particles	... less than 002 mm.	form clay

Types of Soil and their Properties. (1) **Sandy soil** contains more or less 60% of sand particles with a small proportion of clay and silt, usually not exceeding 10% of each. It is well aerated, being very porous; but as it allows easy percolation of water through the large pore spaces it quickly dries up and often remains dry. This soil is loose and light and has no cohesive power. Capillarity decreases in this soil and it can hold only 25% of water of its own weight, when saturated. It contains very little plant food. It can, however, be improved by the

addition of clay, lime or humus. Being loose and porous it helps seed germination and root growth but is not suitable for subsequent growth. (2) **Clay soil** contains over 50% of clay particles. It is compact and heavy. It easily becomes waterlogged, and is badly aerated. Drainage is difficult, and its workability equally so. It is hard and often cracks when dry, but becomes soft and sticky when wet. Capillarity increases considerably in this soil, and it has a great capacity for holding water (40% or more of its own weight), particles being very fine. This soil always contains a considerable amount of plant food, but the root cannot easily penetrate it. The addition of lime or sand improves it and makes it suitable for normal plant growth. (3) **Loam** contains 30-50% of silt and a small amount of clay (5-25%), the rest being sand. It is the best soil for vigorous plant growth and is most suitable for agricultural crops because all the important physical conditions are satisfied—porosity for proper aeration and for percolation (downward movement) of excess water, and capillarity for upward movement of subsoil water. It can hold 50% or a little more of water of its own weight. At the same time it is rich in plant food.

The proportions of the above constituents of the soil can be approximately determined by stirring a small lump of soil in a beaker to which an excess of water has been added, and then pouring the contents into a measuring cylinder. When the mixture is allowed to settle, it is seen that sand particles collect at the bottom, silt higher up, and clay on the top, in three distinct layers. A fine portion of the clay, however, remains suspended in water. Their proportions are then determined and percentages calculated. Humus mostly floats on water.

There are other kinds of soils also. (1) **Calcareous soil** contains over 20% of calcium carbonate which is useful in neutralizing organic acids formed from humus. It is commonly whitish in colour. (2) **Laterite soil** contains a high percentage of iron and aluminium oxides. It is reddish, brownish or yellowish in colour. (3) **Peat soil** contains a high percentage (even up to 80% or 90%) of humus. It is dark in colour, porous and light. The floating garden of Kashmir is made of peat soil.

Soil Water and Soil Air. Ordinarily two-thirds of the pore space occupied by water and one-third occupied by air are found to be suitable for normal growth of most crop plants. An excess of water in the soil chokes its pore space and is, therefore, harmful to plants. Conversely a very low percentage

of water in the soil results in the wilting of plants. The water loosely held by the small soil particles by *capillary force*, with mineral salts dissolved in it, is the water absorbed by the root-hairs.

Water Content of the Soil. To find out the water content of the soil the following procedure may be adopted. Collect from a depth of 0·3-1 m. a small sample of soil by digging the earth, and keep it in a stoppered jar. Take out a small lump from it and weigh it. Heat it at 100°C. for a while, stirring the mass occasionally. All the water will be driven out by then. After cooling take the weight of the soil again. To make sure that all the water has been driven out, heat the same soil over again. A constant weight of the soil will indicate the loss of all the water from it. The difference in weight is the quantity of water originally present in the soil. Then calculate the water content on a percentage basis.

Chemical Nature. Chemically the soil contains a variety of *inorganic salts* such as nitrates, sulphates, phosphates, chlorides, carbonates, etc., of potassium (K), calcium (Ca), magnesium (Mg), sodium (Na) and iron (Fe), and of the 'trace' elements like boron (B), manganese (Mn), copper (Cu), zinc (Zn), aluminium (Al), molybdenum (Mo), etc. A certain amount of *organic compounds*, chiefly proteins and their decomposition products, are also present in the soil. *Humus* (see below) is also present in many soils as a source of *organic food*. *Acidity* or *alkalinity* of the soil is no less important for plant growth than the availability of plant food in the soil. Soils containing a high amount of lime (calcium carbonate) are alkaline, and soils containing a high quantity of humus are acid. These conditions can, however, be altered by the addition of one or the other, as the case may be. Most of the field crops prefer a slightly acid soil. The acid or alkaline nature of the soil may be tested by special chemical indicators. The soil containing a certain amount of lime (calcium carbonate) is said to be calcareous soil. The presence of calcium carbonate in such a soil can be detected by adding strong hydrochloric acid to a small sample of it when effervescence is noticed in it either with the naked eye or under a pocket lens.

Humus. Humus is decomposed vegetable matter (dead roots, trunks, branches and leaves). It forms a dark-coloured surface layer on the ground, often occurring to some depth in forests and swamps. It is very useful both physically and chemically. It is rich in plant food, particularly nitrogen. Humus absorbs and retains water to a considerable extent

(about 190 parts of its own weight). Added to sandy soil it increases its water-holding capacity, and added to clay soil it loosens its compactness and makes it porous for better aeration. Soil containing 5-15% of humus is suitable for agricultural crops. It is mostly the seat of bacterial activities of the soil.

Humus Content of the Soil (ignition method). After heating a lump of soil at 100°C. to drive out the water, cool it in a desiccator and take its weight. Then in a platinum crucible burn the dehydrated soil at a high temperature for about an hour, occasionally stirring the mass. During ignition fumes are seen to escape. (Organic matter becomes converted into ammonia, oxides of nitrogen or free nitrogen, sulphur dioxide and carbon dioxide, and escapes as such.) After complete combustion cool it in a desiccator and then weigh it again. The loss in weight approximately represents the quantity of humus originally present in the soil sample. Then calculate the humus content of the soil on a percentage basis. The residue left after combustion is the incombustible or inorganic matter present in the soil.

Soil Organisms. Various kinds of bacteria are present in the soil, sometimes to the extent of a few million individuals per gram of soil, particularly in the region of organic matter, and many of them are useful agents of soil fertility. Thus nitrifying bacteria convert proteins of dead plants and animals into nitrates, and it is a fact that but for the activity of such bacteria the proteins would remain locked up in the soil as such without being used. Then there are nitrogen-fixing bacteria, ammonifying bacteria, sulphur bacteria and a host of other types in the soil. Fungi are also abundant in the soil, particularly in acidic soil, often replacing bacteria. Like the bacteria they are also useful agents in decomposing proteins. Many algae are also present in the soil. It is now definitely known that many of the blue-green algae fix atmospheric nitrogen in the soil. Among animals the soil-dwellers, such as protozoa, earthworms, rats, etc., are useful agents in altering the soil. The burrowing animals make the soil loose for better aeration and percolation of water.

Fertilizers. Ordinarily the soil contains the necessary salts required by plants. Deficiency, however, sometimes occurs in one or more of them, particularly in nitrogen, phosphorus, potassium and calcium, and to make good this deficiency the use of fertilizers or manures becomes a necessity. Fertilizers are certain chemical substances which when properly added to the soil make it fertile, i.e. enable it to produce more abundantly. Manuring the field for better crop production may

be done by any of the following three methods. (1) Artificial manuring is done by introducing into the soil certain chemical fertilizers, such as ammonium sulphate, superphosphate, leaf compost, bonemeal, oil-cakes, etc., in suitable proportions. It may be mentioned in this connexion that the **Sindri Fertilizer Factory** constructed at Sindri (Bihar) will shortly be producing 400 tonnes of ammonium sulphate daily. (2) Farmyard manuring is done by adding cowdung and organic refuse to the soil. (3) Green (natural) manuring is done by rotation of crops (see p. 212).

A. PHYSIOLOGY OF NUTRITION

CHAPTER 3 *Chemical Composition of the Plant*

The various elements that have entered into the composition of the plant body may be determined by **chemical analyses**, and those essentially required by the plant determined by **water culture experiments**.

i. Chemical Analyses. Chemical analyses of different plants have so far revealed the presence of a long list of elements—over 40—in them, occurring of course in varying proportions. Of these, the following elements have been found to be constantly present in all plants. Analyses of the *organic compounds* as a whole show the presence of carbon (C), hydrogen (H), oxygen (O), nitrogen (N), sulphur (S) and phosphorus (P). Analyses of the *ash* show the presence of potassium (K), calcium (Ca), magnesium (Mg), iron (Fe) and sodium (Na) among the metals, and sulphur (S), phosphorus (P), chlorine (Cl) and silicon (Si) among the non-metals, and also certain other elements in mere traces only known as 'trace' elements such as boron (B), manganese (Mn), zinc (Zn), copper (Cu) and molyb-

denum (Mo.). Aluminium (Al), though not constant, is very widespread in plants.

2. Water Culture Experiments. Water culture experiments are carried out to ascertain (*a*) which of the elements mentioned above are essential, i.e. required by plants for their normal growth, (*b*) which are non-essential, i.e. absorbed by plants only incidentally, and (*c*) which are 'trace' elements, i.e. required in mere traces only. These experiments also help us to understand the nature of chemical compounds suitable for absorption, their particular concentration and the source of supply (soil or air). Water culture experiments consist in growing some seedlings in water containing some known salts in particular proportions, known as **normal cultural solution**, and studying the effect produced on the seedlings with regard to growth and development. A standard solution worked out by Knop, known as **Knop's normal culture solution**, is as follows. Minute doses of salts of 'trace' elements are also to be added.

Potassium nitrate, KNO_3	... 1 gm.
Acid potassium phosphate, KH_2PO_4	... 1 gm.
Magnesium sulphate, MgSO_4	... 1 gm.
Calcium nitrate, $\text{Ca}(\text{NO}_3)_2$... 4 gms.
Ferric chloride solution, FeCl_3	... a few drops
Water	... 1,000 c.c.

This is a stock solution of 0·7% strength. To make a 0·1% solution which is suitable for water culture experiments add 6,000 c.c. of water to the stock solution.

Experiment 1. Water culture experiments. A series of bottles or jars of the same size and shape, marked respectively *A*, *B*, *C*, *D*, etc., and each fitted with a split cork, an appropriate number of seedlings of the same kind and more or less of the same size, and culture solutions of known composition are required for these experiments. Through the split cork a seedling is introduced into each bottle. The bottles are wrapped with black paper and exposed to light. Arrangements should be made for proper aeration of the roots. It is desirable that the culture solution should be renewed fortnightly. Later the following *observations* are made.

In bottle *A* (with normal culture solution) the growth of the seedling is normal. In bottle *B* (the same minus potassium salts) the growth becomes checked and leaves lose their colour. In bottle *C* (the same minus calcium salts) roots do not develop properly and leaves become yellowish, spotted and deformed. In bottle *D* (the same minus magnesium salts) chlorophyll does not develop and the seedling is stunted in growth. In bottle *E* (the same minus iron salts) the seedling becomes chlorotic. In

bottle *F* (the same minus nitrogen compounds) the seedling is weak and straggling, and leaves yellowish.

Inference. The inference that may be finally drawn from the water culture experiments is that the following elements in suitable soluble compounds are essential for normal growth of a plant : K, Ca, Mg, Fe among metals, H, O, N, S, P among non-metals, and certain 'trace' elements, e.g. Mn, Zn, Cu, Mo and B, making a total of 15 elements including C; that free oxygen and carbon dioxide are obtained from the air (and not from the soil); that free nitrogen of the air is of no use to the plant.

Sand Culture Experiments.

To obviate many difficulties in water culture experiments it has become the growing practice with scientists to use sand or charcoal culture. Charcoal is thoroughly washed and powdered. In the case of sand, it is washed, dried and then ignited to remove organic impurities. Normal culture solution is added to any of the two media and growth of the seedling studied. The effect produced on the seedling under the exclusion of a particular element is studied in the same way as in water culture experiments.

Classification of Elements

Essential : metals—K, Ca, Mg and Fe.
non-metals—C, H, O, N, S and P.

Non-essential : metal—Na.

non-metals—Cl and Si.

Trace (essential) : metals—Mn, Zn, Cu and Mo.
non-metal—B.

Hydroponics. Hydroponics or soilless cultivation is the technique of growing plants directly in *normal culture solution* including the essential 'trace' elements without the use of soil, or in pure sand irrigated with this solution. Waterproof earthen vessels, troughs, semi-pucca beds, etc., filled with the solution are commonly used for the purpose, and these are laid out in verandas, backyards, house roofs, etc. Rocky beds, barren areas, etc., where culti-

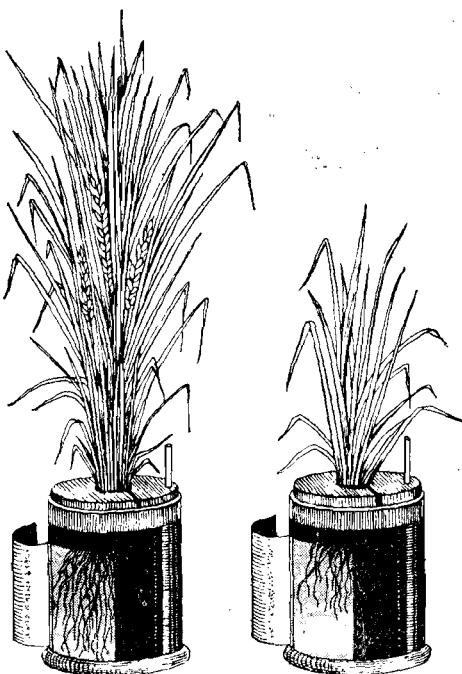

FIG. 321. Water culture experiments; *left*, in normal solution; *right*, in the same minus one of the essential elements.

vation is not possible, are also profitably utilized for hydroponic culture. Hydroponics was established by Geriche of California University in the year 1929. By this method he was able to grow tomato plants to a height of 8m. Hydroponics is now regarded as an established science. At present there are about twenty hydroponic research centres in the world.

ROLE PLAYED BY THE ELEMENTS IN THE PLANT BODY

(1) **Potassium** is abundnatly present in the growing regions. It is essentially a constituent of the protoplasm but is absent from the nucleus and the plastids. Potassium is known to help synthesis of carbohydrates and proteins and also growth of the plant body ; starch grains are not formed in its absence. In the absence of potassium the stem becomes slender and the leaves lose their colour and gradually wither.

(2) **Magnesium** is present in the chlorophyll to the extent of about 5·6% by weight and, therefore, in its absence chlorophyll is not formed, and the plant becomes stunted in growth. It is present to a considerable extent in the seeds of cereals and leguminous plants.

(3) **Calcium** occurs in the cell-wall, particularly in the middle lamella, as calcium pectate. Calcium neutralizes certain organic acids to form insoluble salts such as calcium oxalate ; otherwise the acids would be injurious to the protoplasm. It promotes the growth of roots. Plants like lemon, orange, shaddock, etc., grow well in a soil rich in calcium (lime). Fruits in general, and stone-fruits in particular, require plenty of calcium for their normal development. Plants become stunted in growth in the absence of calcium, and are liable to be diseased.

(4) **Iron** is essential for the formation of chlorophyll although it is not present in the latter. It may be associated with the plastids. Iron is always present in the protoplasm and in the chromatin of the nucleus.

(5-6) **Sulphur and Phosphorus.** Sulphur is present in the protoplasm and enters into the composition of many plant proteins. It is an important constituent of mustard oil. In its absence leaves become chlorotic and the stem slender. Phosphorus is always present in the nucleoprotein, a constituent of nucleus, and in lecithin, a constituent of protoplasm ; it promotes nuclear and cell-divisions. Phosphorus aids in nutrition and hastens maturity and ripening of fruits, parti-

cularly of grains. It promotes the development of the root system and other underground organs.

(7) **Carbon** forms the main bulk—45% or even more—of the dry weight of the plant. It is the predominant constituent of all organic compounds which are, in fact, known as compounds of carbon. Carbon is absorbed from the atmosphere as carbon dioxide. Although carbon dioxide occurs in the air to the extent of only 0·03%, air is still the only source of all the carbon for the plant, as proved by water culture experiments. **Carbon Cycle.** It is to be noted that there is a regular circulation of carbon dioxide and oxygen between the green plant and the atmosphere, and two processes are connected with it: one is photosynthesis and the other is respiration. In photosynthesis *green* plants take in carbon dioxide from the atmosphere *during the daytime* to manufacture food, and they give off oxygen (by the breakdown of water in the process). There is thus a tendency of the atmosphere becoming poorer in carbon dioxide and richer in oxygen. In the reverse process, i.e. in respiration, *all* plants and animals take in oxygen from the atmosphere *at all times*, and by oxidation and decomposition of food they give off carbon dioxide. In the combustion of coal and wood also carbon dioxide is given out to the atmosphere. Thus the atmosphere has a tendency of becoming richer in carbon dioxide and poorer in oxygen. There is thus a regular circulation of carbon dioxide and oxygen between the green plant and the atmosphere, and by the two processes mentioned above the total volumes of these gases are kept constant in the air.

(8) **Nitrogen.** Although nitrogen occurs to the extent of about 78 parts in every 100 parts of air by volume, it is not as a rule utilized by plants in its free state. Nitrogen occurs in the dry substance of the plant to the extent of 1·3% only. Nevertheless, it is indispensable to the life of the plant, as it is an essential constituent of proteins, chlorophyll and protoplasm. Nitrogen is essential for growth, more particularly of leafy herbs like lettuce. In the absence of this element leaves become yellowish.

Nitrogen of the Soil. Nitrogen is present in the soil in the form of *inorganic* and *organic* compounds. The chief forms of inorganic compounds are the nitrates and nitrites of potassium and calcium, as well as ammonia and its

compounds; while the organic compounds are chiefly the proteins. Normally the ammonium compounds present in the soil are made available for the use of the green plants after conversion into nitrate by the action of certain micro-organisms—the nitrifying bacteria—which live in the soil. The process is called **nitrification**. In this process the ammonium compounds are oxidized into nitrate in two stages: (a) these are acted on by the nitrite-bacteria (*Nitrosomonas*) and oxidized into nitrite (-NO_2), and (b) the nitrite thus formed is again acted on by the nitrate-bacteria (*Nitrobacter*) and further oxidized into nitrate (-NO_3). The nitrate thus produced is readily absorbed by green plants. In certain types of soils, however, ammonium compounds are the chief forms in which nitrogen is readily absorbed by plants. A portion of the ammonium compounds, however, is disintegrated by denitrifying bacteria into free nitrogen which then escapes into the atmosphere (**denitrification**).

The chief forms of organic compounds of nitrogen are the various kinds of proteins. Dead bodies of animals and plants containing proteins are decomposed by different putrefying bacteria and also to some extent by certain fungi present in the soil. In the first stage, *in the absence of oxygen*, the proteins are reduced to amino-acids and then to ammonium compounds (**ammonification**) by the putrefying bacteria and fungi; and in the second stage, *in the presence of oxygen*, the ammonium compounds undergo nitrification, as stated above. The nitrate thus produced is readily absorbed by green plants.

Fixation of Atmospheric Nitrogen. The gaseous nitrogen of the air combines with other elements and is ultimately made available to the plants as compounds of nitrogen in the soil. The methods by which the free nitrogen of the air may be fixed are as follows: (1) discharge of electricity in the atmosphere, (2) activity of certain saprophytic bacteria, (3) activity of symbiotic bacteria, and (4) activity of blue-green algae.

1. **Nitrogen Fixation by Electric Discharge.** The free nitrogen of the air to some extent becomes available to the green plants by the discharge of electricity (lightning) during a thunderstorm. Under the influence of electricity nitrogen of the air combines with oxygen to form nitric oxide $\text{-N}_2 + \text{O}_2 = 2\text{NO}$ (nitric oxide). This nitric oxide of the air is finally washed down into the soil by rain as nitric acid (HNO_3) and nitrous acid (HNO_2). In the soil they combine with some metal-like K or Ca and form

corresponding salts—nitrate and nitrite. On an average the rain water brings down to the soil about 4 kilogrammes of nitrogen per year per hectare.

2. Nitrogen Fixation by Saprophytic Bacteria of the Soil. Certain types of soil bacteria, particularly species of *Azotobacter* (aerobic) and *Clostridium* (anaerobic) have the power of fixing free nitrogen of the soil air in their own bodies in the form of amino-acids and finally building up proteins from them. After the death of these bacteria the proteins are released to the soil. In due course these are acted on by the nitrifying bacteria and finally transformed into nitrates which are then made use of by the green plants. The chemistry of nitrogen fixation is not, however, definitely known.

3. Nitrogen Fixation by Symbiotic Bacteria : Nodule Bacteria of *Leguminosae*. Agriculturists have known for a long time that leguminous plants, such as pulses, grown in a soil make it fertile and lead to an increase in the yield of cereals. It was later discovered that the roots of these plants possess some swellings, called **nodules** or **tuberles**, which are infected with some types of nitrogen-fixing bacteria, particularly the different strains of *Rhizobium radicicola*, and these bacteria have the power of fixing the free nitrogen of the soil air in the nodules. Bacteria enter through the tip of the root-hair (fig. 323) and pass into the root-cortex. Bacteria then multiply in number and colonize the cortex. By their activity and possibly also by some kind of secretion the cortical cells become stimulated, and they grow out here and there in small swellings or nodules of varying sizes (fig. 322). Bacteria then fix in these nodules the nitrogen of the soil air in the form of some amino-compounds. A portion of the amino-

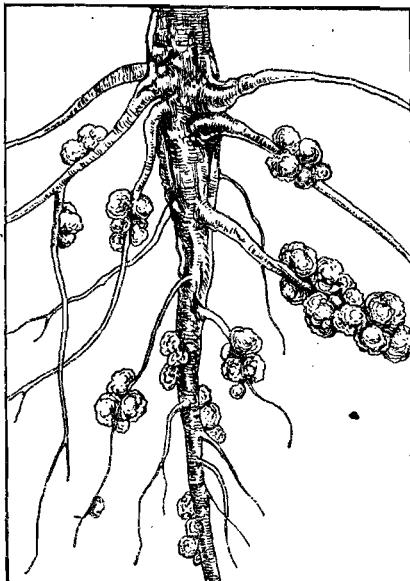

FIG. 322. Nodules of a leguminous plant.

compounds is absorbed into the plant body, another portion is excreted out of the nodules, and the remaining portion remains locked up in the nodules.

Thus the soil becomes richer in nitrogen, more particularly so if the nodule-bearing leguminous plants are ploughed into the soil. The leguminous plants supply the bacteria with carbohydrates, and the bacteria supply the former with nitrogenous food; so this is a case of **symbiosis** (see p. 9).

Nitrogen Cycle. Although plants are continually absorbing salts of nitrogen from the soil it should not be supposed that the nitrogen content of the

soil would sooner or later become exhausted. Under natural conditions the soil soon becomes replenished with this element. This is so because there is a regular circulation of nitrogen through the air, soil, and plants and animals. Nitrogen in the soil is, therefore, inexhaustible. We have already seen how the free nitrogen of the air is brought down into the soil as ultimate products of nitrite and nitrate of some metals. Nitrates are absorbed by plants and made into proteins in their body. Plant proteins are taken up by animals. After the death and decay of animals and plants the proteins contained in their bodies are again converted into nitrates in several stages, as already described (see p. 210), and again absorbed as such by plants. At the same time a portion of the ammonium compounds present in the soil is disintegrated by denitrifying bacteria into free nitrogen or oxides of nitrogen which then escape into the air.

Rotation of Crops. The fixation of atmospheric nitrogen in the soil is of very great agricultural importance. Most crops absorb the nitrogenous compounds from the soil and impoverish it. Leguminous plants, on the other hand, enrich it in nitrogen when their nodule-bearing roots are left in the soil. Thus leguminous crops such as pulses, *Sesbania cannabina* (B. DHAINCHA), cow pea (*Vigna sinensis*), etc., are grown in the field in rotation with the non-leguminous crops such as cereals (rice, wheat, maize, barley, oats, etc.) and millets. For the same reason certain leguminous plants—*Tephrosia* and *Derris*, for example—are grown in tea gardens as nature fertilizers (and also for shade). Root crops, such as turnip, radish, beet, etc., take plenty of potash, calcium and nitrogen from the soil.

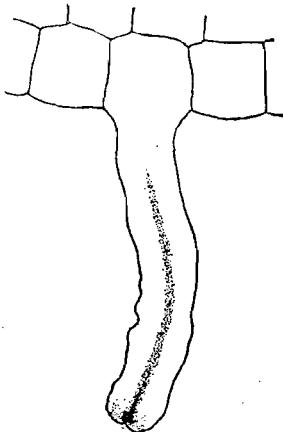

FIG. 323. A root-hair infected with bacteria.

CHAPTER 4 *Absorption of Water and Mineral Salts*

Roots and leaves are the main absorbing organs of plants. Roots absorb water and dissolved mineral or inorganic salts from the soil, while leaves take in gases—oxygen and carbon dioxide—from the atmosphere.

1. Water and Inorganic Salts from the Soil. Green plants absorb water and mineral or inorganic salts from the soil by the unicellular root-hairs which pass irregularly through the interstices of the soil particles and come in close contact with them. Absorption is also carried on by the tender growing regions of the roots. Surrounding each soil particle there is a film of water, thin or sometimes thick, loosely held to it by *capillary force*, with various mineral salts such as nitrates, chlorides, sulphates, phosphates, etc., dissolved in it. This capillary water is readily absorbed by the root-hairs. It is to be noted that water is absorbed in large quantities, always in excess of the requirements of the plant, while the various soluble inorganic salts are absorbed in small quantities in a state of *very dilute solution* by a process called **osmosis** (see p. 214).

Experiment 2. Absorption of water. (a) An interesting experiment may be carried on in the following way. Take a cut branch of a lupin plant with white flowers in a glass cylinder filled with water coloured with eosin. Within a few minutes it will be seen that the white flowers turn pinkish—the colour of eosin—as a result of absorption of coloured water by the cut end of the branch. The *Peperomia* plant may be similarly used and streaks of red noticed through the stem. (b) To demonstrate the **rate of absorption** proceed in the following way. Arrange the experiment as shown in fig. 331 and mark the level of water in the graduated tube. Note every few hours the gradual fall of the water level. At the end calculate the rate of absorption per unit of time. The experiment may be repeated under different conditions of light and temperature and the rates of absorption compared. It will be noted that strong light and high temperature enhance the rates of absorption.

2. Gases from the Atmosphere. Of the various gases present in the air¹ it is only oxygen and carbon dioxide that are absorbed and utilized by the plant. Other gases may enter

¹ **Composition of the Air.** Of 100 parts of air by volume nitrogen occupies 78%, oxygen 21%, carbon dioxide 0·03%, and other gases such as hydrogen, ammonia, ozone, aqueous vapour, etc., occur in traces only.

the plant body, but they are returned unused. Oxygen is absorbed and utilized by all the living cells of the plant for respiration; but carbon dioxide is absorbed by only the green cells for the manufacture of carbohydrates.

Osmosis. There are certain membranes which allow a solvent (water, for example) to pass through them freely but resist the passage of a solute (salt or sugar in solution) so that only a minute quantity of the latter can pass through. On account of this property of selective transmission such membranes are said to be semipermeable or differentially permeable, e.g., parchment paper, fish- or any animal-bladder, egg-membrane, etc. When weak and strong solutions are separated by such a membrane there is a net transfer of the solvent from the weaker solution to the stronger one. *This process of selective transmission of a solvent in preference to the solute through a semi-permeable membrane is termed osmosis.* Osmosis continues until the *hydrostatic pressure* due to the accumulated flow of the solvent has attained a value sufficient to stop further flow. This excess pressure is called the **osmotic pressure** of the stronger solution (see experiment 3). The greater the concentration of a solution the greater would be its osmotic pressure. A familiar example of osmosis is that raisins immersed in water are seen to swell up as a result of endosmosis. Similarly, grapes immersed in a strong solution of sugar or salt (say, 25% or 30%) are seen to shrink.

Importance of Osmosis in Plant Life. Root-hairs absorb water from the soil through the process of osmosis. All the cells of the plant body are saturated with water as a result of cell to cell osmosis. The cortex of the root generates root-pressure by this process. Parenchymatous cells surrounding xylem vessels absorb water from the latter by the same process. Similarly the mesophyll cells of the leaf draw water from the ends of veins generating a suction force. Osmosis gives rise to turgidity which is responsible for some kinds of movements of plant organs (see p. 216).

Experiment 3. Process of osmosis (fig. 324). Take a wide thistle-funnel with a long, narrow stem and close its mouth with parchment paper or fish-bladder. Fill it with strong salt solution a little above its neck and introduce it, stem upwards, into a beaker containing water. Mark the level of the solution in the stem. After an hour or so note that the level of the solution in the stem has gone up. This rise is due to the accumulation of

A B S O R P T I O N O F W A T E R & M I N E R A L S

water in the funnel as a result of a more rapid flow of the water into the thistle-funnel by osmosis (endosmosis) through the membrane. This rise is seen to continue until the level has gone sufficiently high up to exert a hydrostatic pressure on the membrane which then stops further net transfer of water by osmosis. This value of the hydrostatic pressure is equal to the **osmotic pressure** of the solution. At the same time a small quantity of salt also passes out through the membrane.

Parts played by Root-hairs (fig. 325).

In the case of root-hairs which contain some sugars and salts in solution, the cell-sap is stronger than the surrounding soil water. The two fluids (cell-sap and water) are separated by the cell-membrane (cellulose cell-wall + plasma membrane). As a consequence osmosis

is set up. There is a flow of water from the soil into the root-hairs through the intervening cell-membrane (endosmosis).

Osmosis, however, is not in this case a purely physical process. Although the cell-wall is permeable to both the water and the solutes, the plasma membrane is but differentially and selectively permeable, allowing the water to flow in, while checking the sugars and salts of the cell-sap from flowing out. This selective permeability is characteristic of the plasma membrane.

Turgidity. As the cell absorbs more and more water by osmosis it increases in volume, the protoplasm is forced outward against the cell-wall and the latter also becomes much stretched. *The fully expanded condition of a cell with its wall in a state of tension due to excessive accumulation of water is called turgidity.* It will be noted that in a cell in a turgid condition

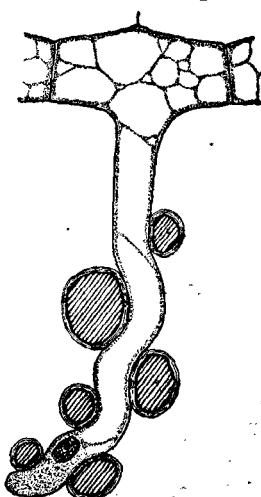

FIG. 325. A root-hair with soil particles adhering to it.

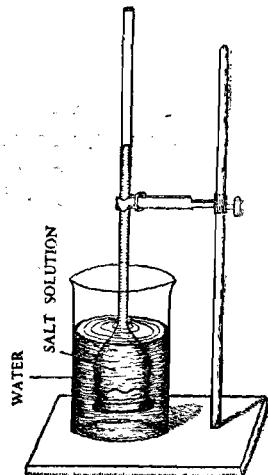

FIG. 324. Experiment on process of osmosis.

two pressures are involved: outward and inward. The outward pressure exerted on the cell-wall by the fluid contents of the cell is called the **turgor pressure**, and the inward pressure exerted on the cell-contents by the stretched cell-wall is called the **wall pressure**. Normally these two pressures counterbalance each other and a state of equilibrium is maintained between them. Turgidity of a cell depends on three factors, viz. (1) formation of osmotically active substances inside the cell, (2) an adequate supply of water, and (3) a semi-permeable membrane.

Importance. A turgid condition is necessary for cell to cell osmosis. Turgidity is always the initial stage of growth. It is responsible for different kinds of movements of plant organs.

Thus movements of the guard-cells of the stomata are due to changes in the turgidity of these cells; similarly, the rising and the falling of the leaf and leaflets of the sensitive plant (*Mimosa*; see fig. 357), Indian telegraph plant (*Desmodium*; see fig. 351) 'sleep' movement in leguminous and some other plants, etc., are brought about by alterations in the turgidity of the cells of the pulvinus. Turgidity of the cells of the root cortex is responsible for forcing the water into the xylem vessels. Turgidity also gives a certain amount of rigidity to the plant, particularly to the growing regions and the soft parts.

Plasmolysis (fig. 326). If a section from a green leaf or a coloured petal, or a *Spirogyra* filament be placed in strong salt or sugar solution (say, 5 or 10%) and observed under the microscope, it will be seen that

FIG. 326. Plasmolysis in a cell of *Vallisneria* leaf under the action of 10% potassium nitrate solution; A, a normal cell; B-D, stages in plasmolysis.

the cell as a whole contracts and more obviously the protoplasm together with the nucleus and the plastids gradually shrinks away from the cell-wall and forms a rounded or irregular mass in the centre ; while the space between the cell-wall and the protoplasmic mass becomes filled with the salt or sugar solution. The reason for such shrinkage of the protoplasm is that the salt or sugar solution being of greater osmotic value than the cell-sap, the cell loses water by outward osmosis. As the water moves out of the cell, the protoplasm and the cell-wall are no longer in a state of tension. Further loss of water evidently results in the shrinkage of the protoplasm. *This shrinkage of the protoplasm from the cell-wall under the action of some strong solution—stronger than that of the cell-sap—is known as plasmolysis.* If the salt or sugar solution be replaced by pure water, soon after plasmolysis, the protoplasm is seen to return to its normal position and the vacuole reappears (deplasmolysis). Potassium nitrate solution (10%) is a very good plasmolysing reagent.

Plasmolysis is a vital phenomenon since dead cells or those killed by boiling for a few minutes show no plasmolysis. The process explains the phenomenon of osmosis ; it shows the permeability of the cell-wall and semi-permeability of the ectoplasm ; it also shows that the protoplasm can retain in its body the osmotically active substances of the sap ; and it indicates the osmotic value of the cell-sap.

CHAPTER 5 *Conduction of Water and Mineral Salts*

ROOT PRESSURE

The water with the mineral salts absorbed from the soil by the root-hairs gradually accumulates in the cortex. As a result the cortical cells become fully *turgid*. Under this condition their elastic walls being much stretched exert pressure on the fluid contents and force out a quantity of them towards the xylem vessels, and the cortical cells become *flaccid*. They again absorb water and become turgid and the process continues. Thus an intermittent pumping action goes on in the cortex of the root, and this pumping action naturally gives rise to a considerable pressure. As a result of this pressure the water is forced into the xylem vessels through the passage cells of

the endodermis, and the unthickened areas and pits that the vessels are provided with. Besides, the lignified walls of the

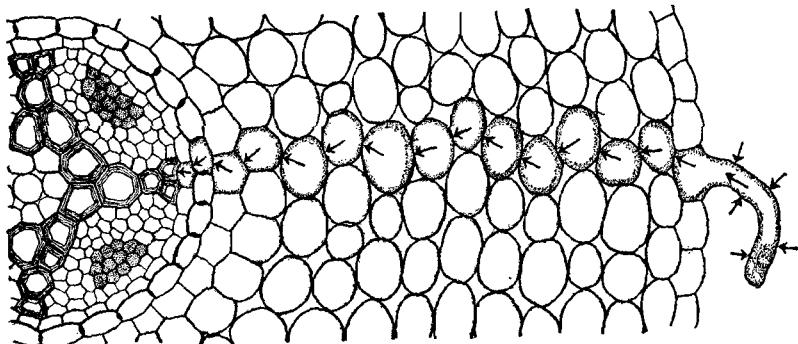

FIG. 327. A root in transection showing the course of water from the root-hair to the xylem.

vessels are also permeable by water. **Root pressure** is thus explained as the pressure exerted on the liquid contents of the cortical cells of the root, under fully turgid condition, forcing a quantity of them into the xylem vessels and through them upwards into the stem up to a certain height.

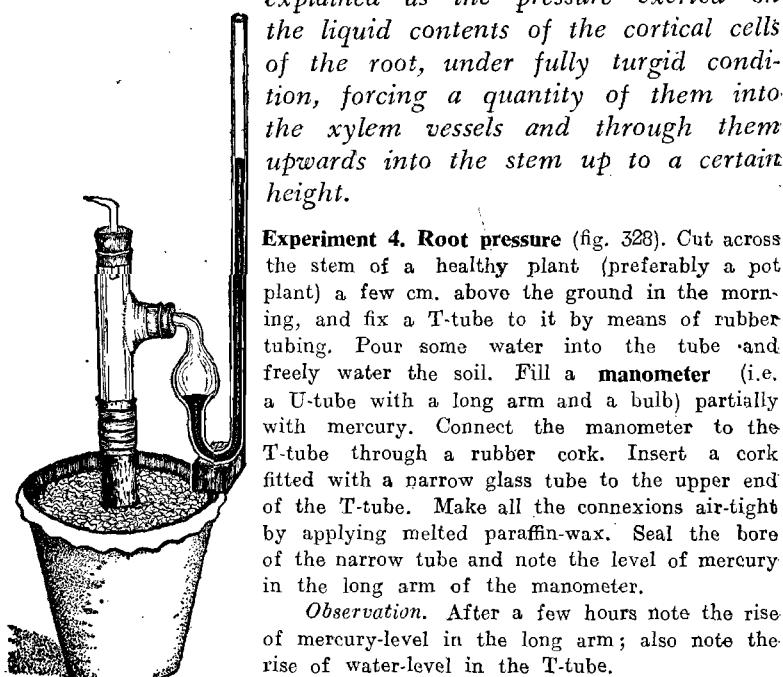

FIG. 328. Experiment on root pressure.

Experiment 4. Root pressure (fig. 328). Cut across the stem of a healthy plant (preferably a pot plant) a few cm. above the ground in the morning, and fix a T-tube to it by means of rubber tubing. Pour some water into the tube and freely water the soil. Fill a manometer (i.e. a U-tube with a long arm and a bulb) partially with mercury. Connect the manometer to the T-tube through a rubber cork. Insert a cork fitted with a narrow glass tube to the upper end of the T-tube. Make all the connexions air-tight by applying melted paraffin-wax. Seal the bore of the narrow tube and note the level of mercury in the long arm of the manometer.

Observation. After a few hours note the rise of mercury-level in the long arm; also note the rise of water-level in the T-tube.

Inference. The rise of mercury is certainly due to accumulation of water in the T-tube and the pressure exerted by it. This phenomenon is evidently due to exudation of water from the cut surface of the stem.

This experiment thus shows that the water is *forced up* through the stem by root pressure.

Sometimes it so happens that certain plants, when cut, pruned, tapped or otherwise wounded, show a flow of sap from the cut ends or surfaces, often with considerable force. This phenomenon is commonly known as *bleeding*, and is often seen in many land plants in the spring, particularly grape vine, some palms, sugar maple, etc.

Conditions affecting Root Pressure. (1) **Temperature.** The temperature of the air as well as of the soil affects root pressure. The warmer the air and the soil, the greater is the activity of the root. (2) **Oxygen.** There must be an adequate supply of oxygen to the roots in the soil for respiration ; otherwise their activity diminishes and may soon come to a standstill. (3) **Moisture in the soil.** A certain amount of moisture must be present in the soil. Within certain limits, the more the better. (4) **Salt in the soil.** Preponderance of salts, making the soil saline, greatly interferes with the absorption of water.

TRANSPIRATION

Plants absorb a large quantity of water from the soil by the root-hairs. Only a part of this water is retained in the plant body for the building up processes, while a greater part of it is lost in the form of water vapour. **Transpiration** is the giving off of water vapour from the internal tissues of living plants through the aerial parts such as the leaves, green shoot, etc., under the influence of sunlight, regulated to some extent by the protoplasm. It is not a simple process of evaporation since it is regulated by the vital activity of the protoplasm and some structural peculiarities of the transpiring organs (see pp. 223-24). A detached leaf is seen to lose water much more rapidly than the one still attached to the plant, and this loss has been found to be 5 or 6 times greater. The total quantity of water that evaporates from a single plant is considerable. Water vapour escapes into the atmosphere either through the stomata or through the thin cuticle. The former is called **stomatal transpiration**, and the latter **cuticular transpiration**. The stomatal transpiration is the rule, and is many times in excess of the cuticular transpiration. At night the stomata being closed, transpiration is checked. **Transpiring Organs.** In dorsiventral leaves the lower surface with a larger number of stomata tran-

spires water more vigorously than the upper ; whereas in isobilateral leaves transpiration is more or less equal from the two surfaces. The guard cells regulate transpiration by partially or completely opening the stoma or by closing it altogether. Lenticels (see fig. 317) are also concerned in the process of transpiration ; water vapour escapes through the loose mass of cells of the lenticel.

Experiment 5. Transpiration : bell-jar experiment. Transpiration can be demonstrated in the following way. A pot plant with its soil-surface covered properly with a sheet of oil-paper is enclosed in a bell-jar and maintained at room temperature for some time. It is then seen that the inner wall of the bell-jar becomes bedewed with moisture.

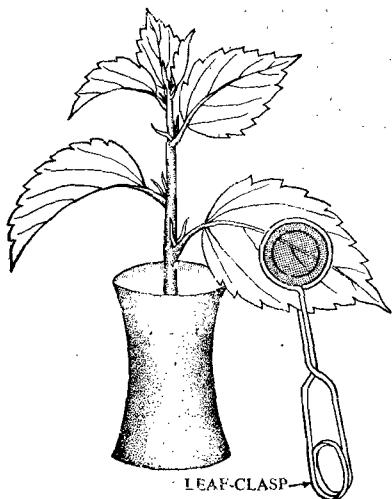

FIG. 329. Unequal transpiration from the two surfaces of a leaf.

the cobalt paper on the lower surface of the leaf turns pink sooner than the one on the upper surface. This change in colouration takes place within a few minutes. This evidently shows that the leaf transpires water more vigorously from the lower surface than from the upper. This is due to the occurrence of a large number of stomata on the lower surface, none or few being present on the upper.

Experiment 7. Measurement of the rate of transpiration current (fig. 330). The apparatus, called a **potometer**, is filled with water, and a branch cut under water is fixed air-tight to the upper wide end of the apparatus through a cork. The distal end of the apparatus is dipped into water contained in a beaker. The water in the beaker may be coloured with eosin. As transpiration goes on, the coloured water is seen to enter the tube. Then remove the end of the tube from the beaker for a while and allow air to enter it. Dip it into water again. An air-bubble formed at the distal end

Experiment 6. Unequal transpiration from the two surfaces of a dorsiventral leaf (fig. 329). Soak small pieces of filter paper or thin blotting paper in 5% solution of cobalt chloride (or cobalt nitrate) and dry them over a flame. The property of cobalt papers is that they are deep blue when dried, but in contact with moisture they turn pink. Place two dried cobalt papers, one on each surface of a thick, healthy leaf, as shown in the figure. Cover them completely with mica pieces or glass slides (or with a leaf-clasp, as shown in the figure), and clamp them properly to the leaf. Then quickly seal the sides with vaseline to prevent atmospheric moisture from coming in contact with the papers. It will be seen that

CONDUCTION OF WATER & MINERAL SALTS 221

of the tube is seen to rise and slowly travel through the horizontal arm of the potometer as a result of suction due to transpiration. Note the time

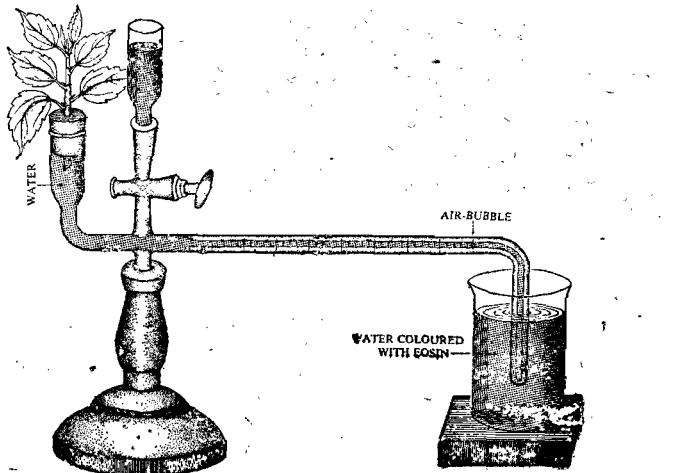

FIG. 330. Potometer experiment on the rate of transpiration current.

that the bubble takes to cover the journey from one end of the graduation to the other, and calculate the rate of transpiration current. By opening the stopcock the bubble may be pushed back and the experiment re-started.

Experiment 8. Relation between transpiration and absorption (fig. 331). A wide-mouthed bottle with a graduated side-tube and a split India-rubber

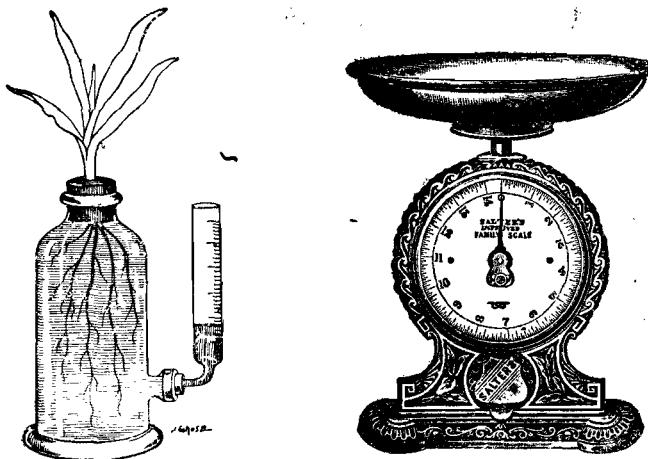

FIG. 331

FIG. 331. Relation between transpiration and absorption. FIG. 332. Compression balance.

cork are required for this experiment. A small rooted plant is introduced through the split cork into the bottle which is filled with water. The level

FIG. 332

of water is noted in the side-tube, and 1 or 2 drops of oil poured into it to prevent evaporation of water from the exposed surface. The connexions are, of course, made air-tight. The whole apparatus is then weighed on a compression balance (fig. 332) and the weight noted. It is seen after a time that the water-level has fallen, indicating the volume of water that has already been absorbed by the plant. The apparatus is then re-weighed. The difference in weight evidently shows the amount of water that has transpired from the leaf-surfaces. If the experiment be continued for a period of 24 hours it will be seen that the volume of water (in c.c.) absorbed is slightly greater than the amount of water (in grams) lost by transpiration ($1 \text{ c.c. of water} = 1 \text{ gm.}$). In this way the relation between transpiration and absorption can be worked out for the various hours of the day and under diverse conditions.

Note. This experiment not only shows the relation between transpiration and absorption, but also separately proves 'absorption' and 'loss of water' by transpiration.

Experiment 9. Suction due to transpiration (fig. 333). Take a **manometer** (i.e. the U-tube with a long arm, as shown in the figure) and fix to its lower

end a long narrow glass tube. Completely fill the tubes with water and insert a leafy shoot, with the cut end kept under water, into one of the arms of the manometer through a rubber cork. Close the other end with a cork. Make all the connexions air-tight by applying melted paraffin-wax. Dip the lower end of the tube into a beaker of mercury. As transpiration goes on water is absorbed, and within a few hours the mercury is seen to rise in the tube to some height. This rise of mercury indicates the suction exerted by transpiration.

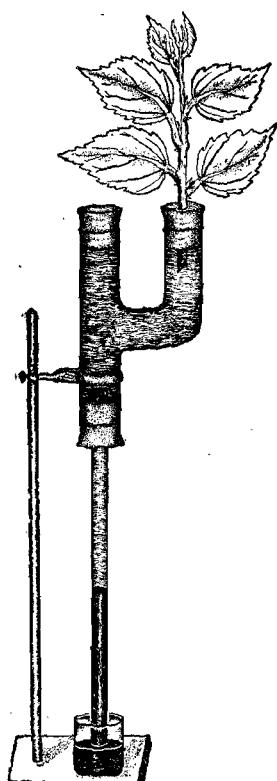

FIG. 333. Suction due to transpiration.

Importance of Transpiration. Transpiration is of vital importance to the plant in many ways. (1) In the first place we find that roots are continually absorbing water from the soil, and this water is several times in excess of the immediate requirement of the plant; the excess is got rid of by transpiration. (2) There is a definite relation between transpiration and absorption. The greater the transpiration, the greater the rate of absorption of water from the soil. (3) Absorption of water helps the intake of

organic salts from the soil. It is, however, not a fact that the greater the transpiration, the greater the rate of absorption of inorganic salts from the soil. As a matter of fact the intake of salts is independent of the quantity of water absorbed. (4) Transpiration secures concentration of the cell-sap and thereby helps osmosis. (5) As a result of transpiration from the leaf-surface a suction force (see experiment 9) is generated which helps water to ascend to the top of lofty trees. (6) Transpiration also helps the distribution of water throughout the plant body. (7) As a result of transpiration, plants become cooler as a considerable amount of latent heat is lost in converting water from a liquid into a gaseous state. In the face of all these advantages the fact cannot be overlooked that excessive transpiration is often a real danger to plant life. Many plants are often seen to dry up and die when excessive transpiration takes place for a prolonged period.

Factors which affect Transpiration. (1) **Light.** Light is the most important factor. During the daytime stomata remain fully open and evaporation of water takes place normally through them. At night stomata remain closed and consequently transpiration is checked. During the daytime again heat-rays of the sun falling directly upon the leaves greatly enhance the rate of transpiration. (2) **Humidity of the Air.** There is an increase or decrease in the rate of transpiration according to whether the air is dry or moist. When the atmosphere is very dry it receives moisture very readily, but when it becomes very moist or saturated it can receive no more water vapour. Loss of water by transpiration is then very slight. (3) **Temperature of the Air.** The higher the temperature, the greater the transpiration ; at high temperatures the water evaporates more freely than at low temperatures. When the two factors, viz. dryness of the air and high temperature, combine transpiration is markedly enhanced. (4) **Wind.** During high wind transpiration becomes very active because the water vapour is instantly removed and the area around the transpiring surface is not allowed to become saturated.

Adaptations to reduce excessive Transpiration. *Anatomical.* Plants have developed many structural devices to reduce excessive transpiration which could be fatal to them. Thick cuticle, multiple epidermis, cutinized hairs and scales, a dense coating of hairs, sunken stomata, temporary closure of stomata,

cork and bark, etc., are some such devices. *Morphological.* The leaf-area is often very much reduced; in extreme cases leaves are modified into spines. The size of the plant is also often reduced. Leaves may be rolled up or variously folded, exposing minimum surface for transpiration. They may also assume a drooping or vertical position to avoid strong sunlight. Deciduous trees shed their leaves in winter as a protection against excessive transpiration, while evergreen trees have their leaves well covered with cuticle.

Exudation of Water. The excess water is also got rid of in many herbaceous plants and undershrubs by a process, commonly called *exudation* or *guttation*. In this process, as seen in rose, balsam, water lettuce, grape vine, many aroids, garden nasturtium, many grasses, etc., water escapes in liquid form at night and accumulates in drops at the ends of veins. These drops of water may be seen in the early morning. Exudation takes place in the absence of transpiration.

ASCENT OF SAP

The water absorbed from the soil by the root-hairs slowly moves up through the plant body to the leaves and the growing regions of the stem and the branches, usually at the rate of 1-2 metres per hour. Two questions naturally arise in this connexion: what is the path of movement of sap and what are the factors responsible for the ascent of sap?

Path of Movement of Sap. The path of movement of sap may be determined in the following way. A small herbaceous plant (e.g. *Peperomia*) or a small branch of a plant (e.g. lupin) may be immersed in eosin solution. After a short time sections, cross and longitudinal, are prepared from it at different heights and examined under the microscope. Sections will show the presence of coloured solution only in the vessels and tracheids. Therefore, there are the elements through which movement of sap, or **transpiration current** as it is called, takes place.

Factors Responsible for the Ascent of Sap. Various theories have been advanced from time to time to explain the ascent of sap, but none has proved satisfactory yet. It is believed that root pressure forces up the water to a certain height and transpiration exerts a suction force on this column of water from above. In short, it may be said that root pressure gives

a 'push' from below and transpiration exerts a 'pull' from above. In this respect transpiration is a more powerful factor. Probable theories regarding the ascent of sap are as follows:

(1) **Root Pressure.** Root pressure is regarded as one of the forces responsible for the ascent of sap. By alternate expansion and contraction of the cortical cells of the root a pumping force is no doubt generated, but this force, which is the root pressure, is only adequate to force up water in herbs, shrubs and low trees, and that too in the absence of transpiration. Root pressure can hardly generate 2 atmospheres of pressure and the maximum height to which a column of water may be raised by this pressure is only 19 metres. The process is also slow and cannot keep pace with the water lost by transpiration. In many plants root pressure is absent or feeble at certain times of the year. Besides, water still rises through the stem if the roots are decapitated and the cut end of the stem dipped into water.

(2) **Cohesion Theory.** According to Dixon and Jolly (1914), the water molecules cohere together and form a long continuous column from the root to the leaf with no air-bubbles in it. This column does not break anywhere in its entire length even under a state of very high tension. Apparently this water-column behaves as a solid column. Then as transpiration takes place from the leaf-surface, a suction force is generated, i.e. a pull is exerted on the water-column at its upper end (see experiment 9). As a result the whole water-column is bodily pulled up. This theory explains how the water can be lifted through the vessels to the height of the tallest trees (over 100 metres).

(3) **Imbibition Theory.** Sachs (1874) suggested that water moves along the walls of xylem vessels (and not through their cavities) as a result of imbibition of water by the solid particles of vessel-walls. But when the cavities of the vessels are artificially blocked with oil, air or gelatin the branches are seen to wilt, showing thereby that the amount of water absorbed by this process cannot at all keep pace with the amount of water lost by transpiration.

(4) **Vitalistic Theory.** It is also believed by some that the activity of living cells, e.g. wood parenchyma and medullary ray cells surrounding xylem, is responsible for the rise of sap through the plant body. The role played by the living cells is like that of relay pumps. The living cells take up water from the vessels at a particular level and then force it again into the vessels at a higher level, and the sap thus rises. Strasburger (1891), however, refuted the idea of vital force by killing the living cells by the application of heat as well as by poisonous chemicals.

(5) **Pulsation Theory.** According to the late Sir J. C. Bose (1923), the ascent of sap is due to active *pulsation* of the internal layer of the cortex abutting upon the endodermis. Conduction of water takes place through this layer even in the absence of root pressure and transpiration. Xylem vessels being dead and inactive no pulsation is exhibited by them, and these were regarded by him as only reservoirs of water. All the living cells exhibit pulsation to a greater or less extent, but the activity of the internal cortex is exceptionally great. Anatomical and experimental evidence, however, does not support this view.

CHAPTER 6 *Manufacture of Food*

Food of Plants. Food consists of certain organic substances which are more or less directly utilized by the living organisms for their nourishment. In this respect there is hardly any difference between the food of plants and that of animals. Such substances are **carbohydrates**, **proteins**, and **fats** and **oils**. Animals, non-green plants and non-green cells of plants have to depend directly or indirectly on the organic food prepared by the chloroplast-bearing cells of green plants. It is evident, therefore, that green plants hold a vital position so far as the living world is concerned.

I. CARBOHYDRATES

Photosynthesis. *Photosynthesis (photo, light ; synthesis, building up) consists in the building up of simple carbohydrates such as sugars in the green leaf by the chloroplasts in the presence of sunlight (as a source of energy) from carbon dioxide and water absorbed from the air and the soil respectively.* The process is accompanied by a liberation of oxygen (see experiment 10). The volume of oxygen liberated has been found to be equal to the volume of carbon dioxide absorbed. But it is to be noted that all the oxygen liberated in the process is released exclusively from water (H_2O) and not from carbon dioxide (CO_2), as first proved by Hill in 1937 and later by others by using radioactive oxygen, O^{18} , in water (H_2O^{18}). Oxygen escapes from the plant body through the stomata. This formation of carbohydrates, commonly called **carbon-assimilation**, is the monopoly of green plants only, chlorophyll being indispensable for the process. By this process not only are simple carbohydrates formed but also a considerable amount of radiant (light) energy absorbed from sunlight is stored up as potential chemical energy in the organic substances formed. It must be noted that photosynthesis takes place only in the green cells and, therefore, mainly in the leaf and to some extent also in the green shoot.

Mechanism of Photosynthesis. The intermediate chemical stages in the process still remain a mystery. Numerous researches carried out over a long period have failed to trace

the different chemical reactions involved in the production of carbohydrates from carbon dioxide (CO_2) and water (H_2O), and this has led to a great deal of speculation. Photosynthesis takes place in a series of chemical reactions—some are photochemical requiring light energy and some are chemical or enzymic requiring a particular temperature. Chlorophyll no doubt is indispensable for photosynthesis, but it is not known what exact role it plays in the process except that (a) it absorbs radiant (light) energy and possibly also transfers this energy to the photosynthetic products, and (b) it acts as a catalytic agent, itself undergoing no change during the photosynthetic process. External factors like light, carbon dioxide and temperature are most essential for proper functioning of the chloroplasts. Several enzymes also play a part in successive stages of the process.

In recent years with the discovery of radioactive elements, particularly radioactive carbon, C^{14} , it has been possible to trace at least some of the compounds through which the carbon dioxide passes on its way to the final products formed during the process of photosynthesis. This is called the 'tracer' method. Thus in 1950 Benson and Calvin by using C^{14}O_2 (with radioactive carbon in it) succeeded in tracing it through some of the intermediate stages of photosynthesis. They found that when the period of photosynthesis, i.e. the period of exposure to light, was shortened to a few seconds a detectable quantity of phosphoglyceric acid was formed. Phosphoglyceric acid is, therefore, the first stable intermediate product formed in photosynthesis. It is a 3-carbon compound and possibly it is formed from an unknown 2-carbon compound. The radioactive carbon used in the experiments could be traced in the phosphoglyceric acid and finally in the sugar formed in the process. But exactly how sugar appears is not clear. It is possible that the union of two such 3-carbon compounds produces a 6-carbon compound, i.e. sugar. The over-all reaction may be represented thus: $6\text{CO}_2 + 12\text{H}_2\text{O} \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{H}_2\text{O} + 6\text{O}_2$.

Photosynthesis as a whole resolves itself into two types of reactions—light and dark. The process of photosynthesis begins with the absorption of light energy by chlorophyll and utilization of this energy in breaking up water (H_2O) into oxygen and hydrogen. The splitting of water is possibly the only *light reaction*. Oxygen escapes, while hydrogen is stored in the chloroplasts in combination with some unknown com-

pound which acts as an acceptor of hydrogen. By this process the light energy is converted into potential chemical energy. Next, hydrogen is transferred to CO_2 (which now acts as an acceptor of hydrogen) to form a 3-carbon compound—phosphoglyceric acid, as stated before. Finally the phosphoglyceric acid becomes transformed into sugar. All the reactions from the reduction of CO_2 (i.e. addition of hydrogen) to the formation of sugar and starch are *dark reactions*. Nearly the whole of CO_2 taken up in photosynthesis enters into the composition of sugar. Sugar is almost immediately converted into starch.

End Products in Photosynthesis. Oxygen and starch are the final products formed in photosynthesis. Oxygen escapes from the leaf (see experiment 10) but starch accumulates in it (see experiment 11). Starch may be detected in the following way. In the evening collect one or more leaves and bleach them with methylated spirit. Then dip them into iodine solution. They are seen to turn bluish-black in colour indicating the presence of starch grains. Starch is insoluble in water. At night it is converted into sugar by the action of an enzyme known as **diastase** and translocated to storage organs. In the storage tissues sugar is reconverted into starch by the leucoplasts.

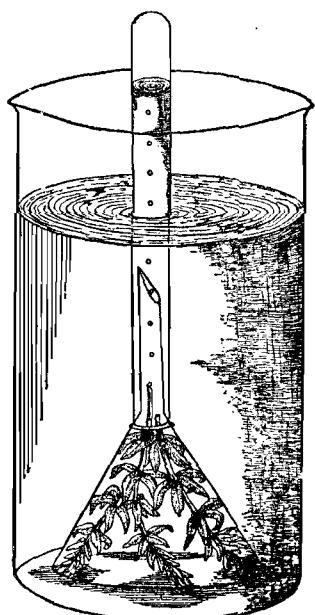

FIG. 334. Evolution of oxygen bubbles in photosynthesis of a water plant (*Hydrilla*).

✓ **Experiment 10. Photosynthesis : to show that oxygen is given off during photosynthesis** (fig. 334). Place some cut branches of *Hydrilla* (an aquatic plant) under cover of a funnel in a large beaker filled with water. Add a pinch of soda bicarbonate as a source of carbon dioxide. Invert over the funnel a test-tube filled with water. Expose the apparatus to bright sunlight. Within a few minutes streams of gas bubbles will be seen to rise from the cut ends of the branches and collect in the test-tube by displacing the water. If the apparatus be removed to a dark or semi-dark room or covered with a black paper or cloth no bubbles are seen to come out. Then remove the test-tube with the gas to pyrogallate solution. It rises and completely fills up the tube. Pyrogallate solution absorbs oxygen. The gas in the tube is, therefore, oxygen.

Experiment 11. Photosynthesis : to demonstrate that starch is formed in photosynthesis (figs. 335-6). Select a healthy green leaf of a plant *in situ* and cover a portion of it on both sides with two uniform pieces of black paper, fixed in position with two paper clips or soft wooden clips either in the morning before the sun rises or the previous evening, so that the experiment is performed with a starch-free leaf. Now expose the plant to light for the whole day. Then collect the leaf and decolorize it with methylated spirit. Dip it into iodine solution for a minute or so. Note that the exposed portions turn blue or black showing the presence of starch, while the screened portion turns yellowish brown, there being no starch formed in it; this yellowish brown colour is due to the action of iodine solution on protoplasm and cellulose.

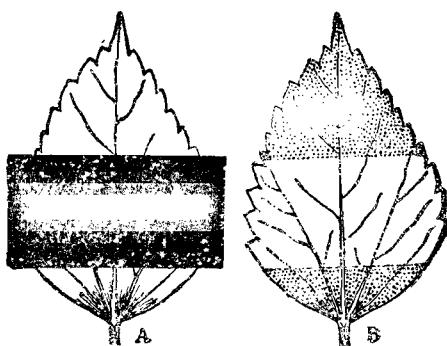

FIG. 335. Formation of starch grains in photosynthesis of land plants. *A*, leaf partially covered with black paper; *B*, covered portion without starch grains; uncovered portions with plenty of them.

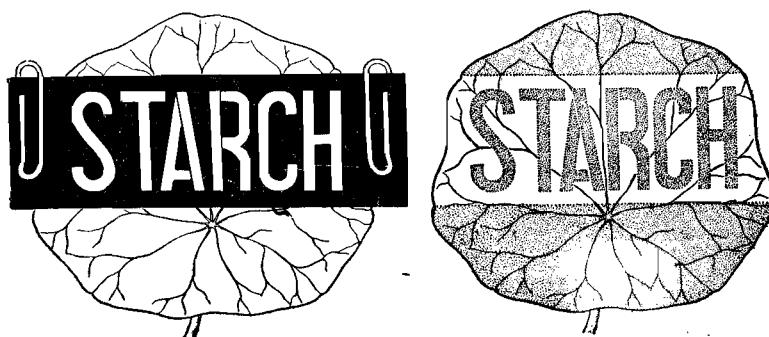

FIG. 336. Starch print in photosynthesis.

A very interesting experiment known as the **starch print** (fig. 336) may be carried out in the following way. A stencil (which may be a blackened thin tin plate or a black paper) with the letters S T A R C H punched or cut in it is used for this purpose, the procedure being the same as described under experiment 11. Later, when the leaf is decolorized and treated with iodine solution, the print of S T A R C H will stand out boldly in black on the bleached leaf owing to the formation of starch grains which have turned black by contact with iodine.

Instead of loose black paper or stencil a **light-screen**, as shown in fig. 337,

may be used to cover a portion of the leaf. The advantage of the light-screen is that it allows free ventilation, while it cuts off all light.

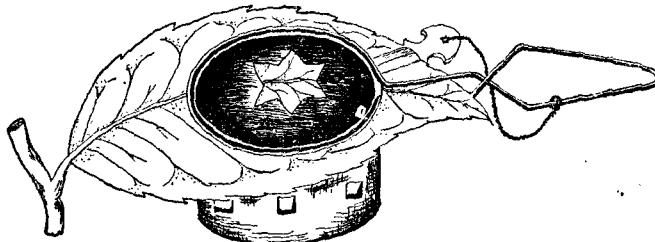

FIG. 337. A light-screen.

Experiment 12. To show that plants cannot photosynthesize unless carbon dioxide is available : Moll's experiment (fig. 338). Take a wide-mouthed bottle and a split cork of appropriate size. Pour a small quantity of dilute caustic potash solution into the bottle.

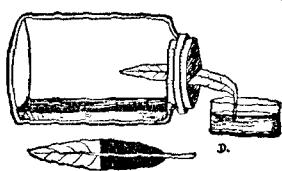

FIG. 338. Moll's experiment on photosynthesis.

Before sunrise cut a healthy green leaf, evidently starch-free, and place it—half inside the bottle and half outside—between the two halves of the split cork. Lay the bottle flat on a wooden tray, with the petiole dipped into a dish of water. Smear the edges of the split cork with vaseline to make the bottle air-tight. The tray with the bottle and dish is then exposed to direct sunlight till the evening. Then remove the leaf, decolorize it with methylated spirit and dip it into iodine solution. It will be seen that the portion of the leaf lying outside the bottle turns black; while the portion inside the bottle turns yellowish. This evidently shows that no starch grains are formed when carbon dioxide is not available, all the carbon dioxide contained in the bottle having been absorbed by the caustic potash solution.

Experiment 13. To show that chlorophyll is essential for photosynthesis. Select a garden croton plant with variegated leaves. Cut out a small branch from it and dip the cut end into water in a bottle. Keep it in a dark room for 1 or 2 days to free the leaves of starch grains. Then mark the green portions in 1 or 2 leaves, and expose the branch to bright sunlight for the whole day. In the evening collect the marked leaves, decolorize them with methylated spirit and dip them into iodine solution for a few minutes. Note that only the green portions of the leaf turn black indicating the presence of starch grains; while the non-green portions turn yellowish. It is, therefore, evident that without chlorophyll photosynthesis cannot take place.

Conditions necessary for Photosynthesis. Light intensity, temperature and carbon dioxide concentration of the air are the three most important external conditions for photosynthesis and its rate.

(i) **Light.** This is the most important condition for photosynthesis. Formation of carbohydrates cannot take place un-

less light is admitted to the chloroplasts (see experiments 10 & 11). The rate of photosynthesis also varies according to the intensity of light.

(2) **Carbon dioxide.** Carbon dioxide of the air is the source of all the carbon for the various organic products formed in the plant, such as sugar, starch, etc., and, therefore, the process is in abeyance if carbon dioxide is not available to the plant (see experiment 12). Under favourable conditions of light and temperature if carbon dioxide concentration rises from 0.03 per cent in the air to 0.1 per cent or even more, carbohydrate formation greatly increases.

(3) **Water.** Water is indispensable for photosynthesis because water and carbon dioxide undergo chemical changes leading to the formation of carbohydrates under the influence of chloroplasts and in the presence of sunlight. It is, however, a fact that less than 1 per cent of the water absorbed by the roots is utilized in photosynthesis.

(4) **Temperature.** Photosynthesis takes place within a wide range of temperature. It goes on even when the temperature is below the freezing point of water, but the maximum temperature lies at about 45°C . The optimum temperature, i.e. the most favourable temperature for photosynthesis, may be stated to be 35°C .

(5) **Chlorophyll.** This is essential for photosynthesis ; the plastids are powerless in this respect without the presence of chlorophyll. For the same reason non-green parts of plants cannot photosynthesize (see experiment 13). Fungi and saprophytic and parasitic phanerogams have altogether lost this power, being devoid of chlorophyll.

(6) **Potassium.** Potassium helps synthesis of carbohydrates and, therefore, in its absence starch grains are not formed. Potassium does not enter into the composition of carbohydrates but acts as a catalyst helping in their synthesis.

Conditions necessary for the Formation of Chlorophyll. A number of factors, both internal and external, are responsible for the formation of chlorophyll. In the absence of any of them chlorophyll synthesis is in abeyance.

(1) **Light.** Without light chlorophyll cannot develop ; continued absence of light decomposes chlorophyll, and the plants become *etiolated*, i.e. pale, sickly and drawn out (see fig. 349). Very strong light decomposes chlorophyll in the leaf, particularly in shade-loving plants.

(2) **Temperature.** Chlorophyll develops within a wide range of temperature; very high temperature ($45\text{-}48^{\circ}\text{C}.$), however, decomposes chlorophyll.

(3) **Iron, Magnesium and Manganese.** In the absence of the salts of these metals chlorophyll is not formed, and seedlings assume a sickly yellow appearance. In this condition they are said to be chlorotic. Of these metals it is only magnesium that enters into the composition of chlorophyll.

(4) **Nitrogen.** Nitrogen enters into the composition of chlorophyll and, therefore, in the absence of nitrogen chlorophyll fails to develop.

(5) **Water.** Leaves, when they dry up in the absence of water, are seen to lose their green colour. Desiccation thus brings about decomposition of chlorophyll. In prolonged droughts the leaves of many plants turn brownish in colour.

(6) **Oxygen.** This is also necessary for the formation of chlorophyll. Etiolated seedlings fail to develop chlorophyll in the absence of oxygen, even when these are exposed to sunlight.

(7) **Carbohydrates.** Cane-sugar, grape-sugar, etc., are also necessary for the formation of chlorophyll. Etiolated leaves without soluble carbohydrates in them, develop chlorophyll and turn green in colour when floated on sugar solution.

(8) **Heredity.** This is a powerful factor and determines the formation of chlorophyll in the offspring. Familiar examples are those with multi-coloured leaves, e.g. garden crotons, aroids (e.g. *Caladium*), amaranth, *Coleus*, etc.

Chemistry of Chlorophyll. Chlorophyll is a mixture of four different pigments, as follows :

- 1 Chlorophyll *a*, $\text{C}_{55}\text{H}_{72}\text{O}_5\text{N}_4\text{Mg}$ —a blue-black micro-crystalline solid.
- 2 Chlorophyll *b*, $\text{C}_{55}\text{H}_{70}\text{O}_6\text{N}_4\text{Mg}$ —a green-black micro-crystalline solid.
- 3 Carotene, $\text{C}_{40}\text{H}_{56}$ —an orange-red crystalline solid.
- 4 Xanthophyll, $\text{C}_{40}\text{H}_{56}\text{O}_2$ —a yellow crystalline solid.

II. PROTEINS

Nature of Proteins. These are very complex organic nitrogenous compounds found in plants. Analyses of proteins show that carbon, hydrogen, oxygen, nitrogen, and often sulphur and sometimes phosphorus enter into their composition, but we know little about their molecular structure. Protein molecules are very large and extremely complex, consisting of hundreds or thousands of atoms, and are composed of several chains of amino-acid molecules. Various kinds of proteins

are found in plants. Amino-acids are the initial stages in the formation of proteins, and are also the decomposition products of the latter.

Synthesis of Proteins. Proteins are normally formed from nitrates absorbed from the soil. But the chemical reactions leading to the formation of these complex compounds are only imperfectly known. Protein synthesis mostly takes place in the meristematic and storage tissues, and also in all active cells of the plant body. Light, however, is not necessary for this process. It is believed that the whole process of protein synthesis takes place in three different stages. (a) **Reduction of Nitrates.** Nitrates, after they are absorbed into the plant body, are first reduced to nitrites, and the nitrites further reduced to ammonia (amino group, -NH₂). This reduction takes place either in the root or in the leaf under the action of some enzymes. (b) **Synthesis of Amino-acids.** This ammonia (amino group, -NH₂) then combines with sugar or some of its intermediate or decomposition products (formed during photosynthesis and respiration) as sources of carbon, hydrogen and oxygen, and amino-acids are built out of them. There are over 20 different amino-acids known to be constituents of plant proteins. Amino-acids are mainly formed in leaves and stem-tips, and from there they may travel to any part of the plant body. (c) **Synthesis of Proteins.** A protein molecule may be finally formed by linkage of hundreds or thousands of amino-acid molecules which may be arranged in the protein molecule in practically an infinite variety of ways. Complex proteins contain sulphur and phosphorus also. These elements are supplied by sulphates and phosphates obtained from the soil. Proteins may break down into amino-acids which may again combine into proteins.

III. FATS AND OILS

The different stages in the formation of fats and oils are not clear. It is believed that they are synthesized from glycerine and fatty acids under the action of the enzyme *lipase*. Both glycerine and fatty acids are derived from carbohydrates. The process is independent of light and chlorophyll. See also p. 145.

CHAPTER 7 *Special Modes of Nutrition*

Green plants are **autotrophic** (*autos*, self; *trophe*, food) or self-nourishing, that is, they are able to manufacture carbohydrates from raw or inorganic materials and thus nourish themselves. Non-green plants on the other hand are **heterotrophic** (*heteros*, different), that is, they cannot prepare carbohydrates and nourish themselves. They get their supply of carbohydrate food from different sources. They can, however, prepare other kinds of food. Heterotrophic plants are parasites, when they depend on other living plants or animals, and saprophytes, when they depend on the organic material present in the soil or in the dead bodies of plants and animals. Their nature and mode of nutrition have already been discussed (see pp. 6-9).

Carnivorous Plants. These plants are known to capture lower animals of various kinds, particularly insects. They digest the prey and absorb the nitrogenous products (proteins) from its body. Digestion is extra-cellular in all carnivorous plants. Being green in colour, they can manufacture their own carbohydrate food. Altogether over 450 species of carnivorous plants have till now been discovered representing 15 genera belonging to 6 families ; of them over 30 species occur in India. According to the mode of catching the prey they may be classified into four groups.

(a) Plants with sensitive glandular hairs on the leaf-surface, secreting a sweet sticky fluid, e.g. sundew (*Drosera*).

(b) Plants with special sensitive hairs—trigger hairs—on the leaf-surface, e.g. Venus' fly-trap and *Aldrovanda*.

(c) Plants with leaves modified into pitchers, e.g. pitcher plant (*Nepenthes*).

(d) Plants with leaf-segments modified into bladders, e.g. bladderwort. Bladderwort and *Aldrovanda* are aquatic.

(1) **Sundew** (*Drosera*; fig. 339)—90 sp. ; only 3 sp. in India. They are small herbs, a few to many cm. in height. Each leaf is covered on the upper surface with numerous glandular hairs known as the **tentacles**. Each gland secretes a sticky fluid which glitters in the sun like dew-drops and hence the name 'sundew'. When any insect, attracted by the glistening fluid, which is possibly mistaken for honey, alights on the leaf, it gets entangled in the sticky fluid, and the tentacles bend

down on it from all sides and cover it. When it is suffocated to death the process of digestion begins. The glands secrete an enzyme, called *pepsin hydrochloric acid*, which acts on the insect and changes the proteins in its body into soluble and simple forms. The carbonaceous materials are rejected in the form of waste products. If the tentacles are poked with any hard object, they show no movement. A bit of raw meat placed on the leaf, however, induces movement.

(2) **Venus Fly-trap** (*Dionaea*; fig. 340)—1 sp. The plant is a native of the U.S.A. It is herbaceous in nature and grows in damp mossy places. Each half of the leaf-blade is provided with three long pointed hairs—trigger hairs—placed triangularly on the leaf-surface. The hairs are extremely sensitive from base to apex. The slightest touch.

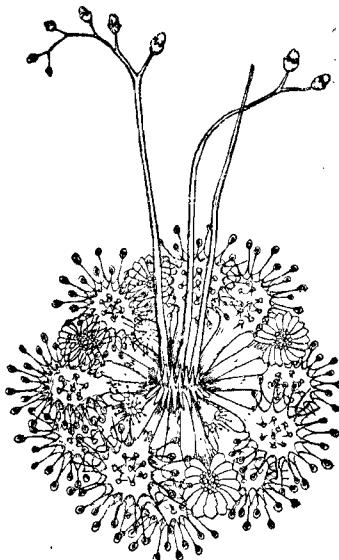

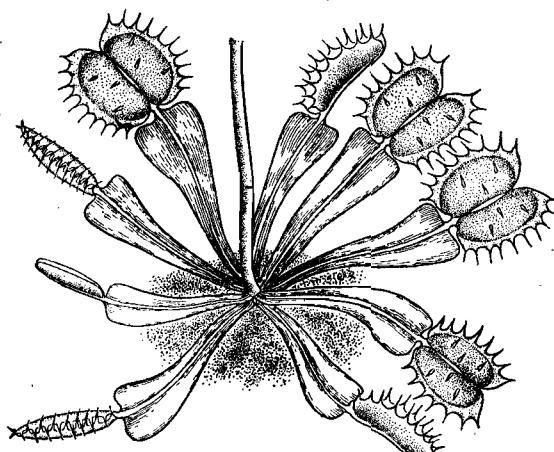

FIG. 339. Sundew (*Drosera*).

FIG. 340.

Venus'
fly-trap
(*Dionaea*).

to any of these hairs is sufficient to bring about a sudden closure of the leaf-blade, the mid-rib acting as the hinge. The upper surface of the leaf is thickly covered with reddish-

digestive glands. When the insect is caught, or any nitrogenous material such as meat, fish, etc., placed on the leaf, it closes suddenly and the glands begin to secrete *pepsin hydrochloric acid*. The enzyme then brings about the digestion of proteins.

(3) **Aldrovanda** (figs. 341-2)—1 sp. This plant is very widely distributed over the earth. It has been found in abundance in the salt-lakes of the Sundarbans, the salt-marshes south of

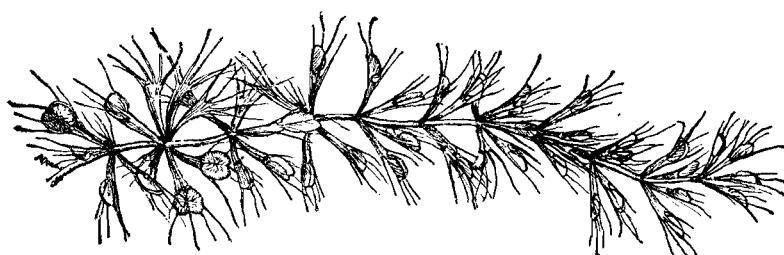

FIG. 341. *Aldrovanda*.

Calcutta, the freshwater 'jheels' of East Pakistan and in several tanks in Manipur. *Aldrovanda* may be regarded as a miniature *Dionaea* in some respects. It is a rootless, free-floating plant with whorls of leaves. The mechanism for catching prey is practically the same as that of *Dionaea*, but instead of only six sensitive hairs there are a number of them here on either side of the mid-rib, and the leaf is protected by some bristles. There are, of course, numerous digestive glands on the upper surface of the leaf, and the margins are beset with minute teeth pointing inwards.

(4) **Pitcher Plant (*Nepenthes*)** (figs. 343 & 120-21)—60 sp; only

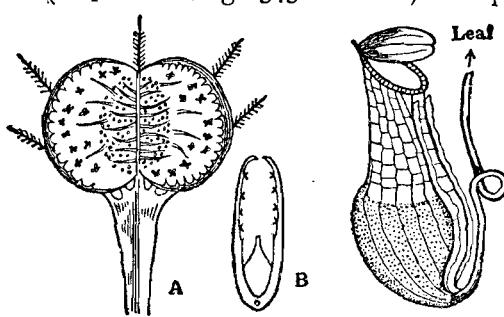

FIG. 342

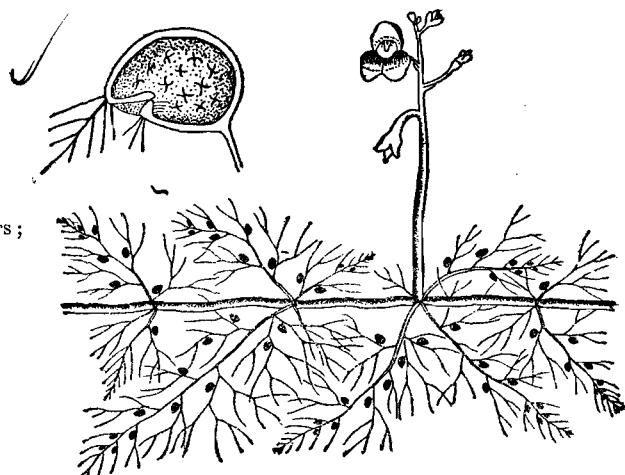

FIG. 343

1 sp. (*N. khasiana*) in India (in the Khasi, Jaintia and Garo hills). Pitcher plants are climbing herbs or undershrubs which

often climb by means of the tendrillar stalk of the pitcher. Each pitcher varies from 10-20 centimetres and sometimes more in height. The mouth of the young pitcher remains closed by a lid which opens afterwards and stands more or less erect. Below the mouth the inside of the pitcher is covered with numerous smooth, sharp hairs, all pointing downwards. Lower down, the inner surface is studded with numerous, large, digestive glands. The pitcher is also partially filled with a fluid. Animals, as they enter, slip down the smooth surface, and are drowned in the fluid. After their death the process of digestion commences. The digestive agent secreted by the glands is in the nature of a *trypsin* which digests proteins into peptones and the peptones into amines. Amines are readily absorbed by the pitcher. Bits of egg-white, meat, etc., dropped into the pitcher, as was first found by Hooker, are seen to become dissolved and ultimately absorbed in the form of amines. Carbohydrates and other materials remain undigested in the pitcher as waste products.

(5) **Bladderwort** (*Utricularia*; fig. 344)—210 sp.; over 20 sp. in India. They are mostly floating or slightly submerged, rootless, aquatic herbs; there are a few terrestrial species also. The leaves are very much segmented, looking like roots except

FIG. 344.
Bladderwort
(*Utricularia*)
with many
smaller bladders;
top, a bladder
in section
(magnified).

that they are green in colour. Some of these segments become transformed into bladders. Each bladder is about 3-5 mm. in diameter and is provided with a trap-door entrance. The trap-door acts as a sort of valve opening only inwards when pushed from outside. Very small aquatic animals enter by pushing the

trap-door. Once inside the trap (bladder) there is no escape for them. The inner surface of the bladder is dotted all over with numerous digestive glands. After the death of the animals the process of digestion begins.

CHAPTER 8 *Translocation and Storage of Food*

Translocation. Food materials are prepared mostly in the leaves. From there they are translocated to the storage organs which often lie at a considerable distance. For this purpose there are definite and distinct channels extending through the whole length of the plant body. These are the sieve-tubes and associated cells. Through them soluble proteins, amines, amino-acids and sugars travel downward to the storage organs. Such materials can easily pass through the perforated sieve-plates. The protoplasmic threads extending through the pores in the sieve-plates also help in this respect. In the storage organs these substances are converted into insoluble (complex) proteins and starch grains, and stored up as such.

Later during the period of active growth—formation of buds and flowers—the various forms of stored food are rendered soluble and, therefore, suitable for travelling. Now an upward movement of the soluble food materials takes place through the phloem and finally they are brought to the growing organs. At this time of active growth a part of the food also moves upward through the xylem. The forces responsible for the downward or upward movement of food through the phloem are not known. That the phloem is definitely the principal channel for conduction of food can be proved by chemical analysis of its contents. Such analysis reveals the presence of soluble carbohydrates (sugars), proteins and other nitrogenous compounds in it.

Storage. Food is prepared in excess of the immediate need of plants. This surplus food exists in plants in two conditions—either *suitable for travelling* or *suitable for storage*. The travelling form is characterized by *solubility*, and the storage form by *insolubility* in the cell-sap.

Storage Tissues. Tissues meant for storage of food are mostly made of living parenchymatous cells with thin cellulose walls.

If the walls are thick they are provided with many simple pits in them. All parts made of large-celled parenchyma always contain a certain amount of stored food. The cortex of roots is particularly rich in it, as also are the large pith of the monocotyledonous root and that of the dicotyledonous stem. There is also a quantity of food stored up in the endodermis, medullary rays and xylem parenchyma of the stem, and border parenchyma of the leaf. **Storage Organs.** Food materials are stored up in the endosperm or in the thick cotyledons of the seed for the development and growth of the embryo. In the fleshy pericarp of the fruit there is a considerable amount of food stored up. Food is specially stored up in the fleshy roots such as the fusiform, napiform, conical and other roots, and in the underground modified stems such as the rhizome, tuber, corm, etc. All fleshy stems and leaves, as in Indian aloe (*Aloe vera*), American aloe (*Agave*), purslane (*Portulaca*), etc., and fleshy scales of onion always contain a store of food in them. The swollen stem-base of kohl-rabi also contains stored food.

Forms of Stored Food. The various forms in which the food materials are stored in these different organs and tissues may now be considered. The food materials are carbohydrates, proteins, and fats and oils (see also pp. 140-45). Among the carbohydrates **starch** is most abundant in almost all the storage organs ; **glucose** accumulates as such in grapes to the extent 12-15%, and **sucrose** in sugarcane and beet to the extent of 10-15% and 10-20% respectively ; **inulin** in the tuberous roots of *Dahlia* ; **reserve cellulose** (see fig. 254) in the endosperm of date seed, vegetable ivory-palm seed, etc. ; and **glycogen** in fungi. Among the nitrogenous materials various kinds of **proteins**, particularly **aleurone grains**, are found in both starchy and oily seeds but bigger aleurone grains occur in oily seeds ; pulses are rich in proteins ; while amino-compounds are scarce in storage organs. **Fats and oils** are found in almost all living cells ; they are specially common, however, in seeds and fruits. In oily seeds very little carbohydrate is found.

Food Stored in the Seed. There is always a considerable amount of food stored up in the cotyledons and in the endosperm of the seed for the use of the embryo as it grows. Food materials occur there in insoluble forms and these are first digested, i.e. rendered soluble and chemically simpler under

the action of specific enzymes (see next chapter), and then utilized by the embryo for its nutrition and growth. Common forms of such food materials are the following. (1) **Starch** is a very common form of carbohydrate stored up in the seed. Cereals such as rice, wheat, maize, oat, barley, etc., are particularly rich in starch. (2) **Reserve cellulose** is deposited as thickened cell-walls of the endosperm of many palm seeds, e.g. date-palm, betel-nut-palm, nipa-palm, vegetable ivory-palm, etc. (3) **Oils** are deposited in most seeds to a greater or less extent. There is a special deposit of them in seeds like groundnut, gingelly, coconut, castor, safflower, etc. (4) **Proteins** also occur in all seeds in varying quantities. In seeds like pulses they occur in fairly high percentage. Soybean contains 42-47% of proteins. Oily seeds also contain a high percentage of proteins, e.g. castor seed.

CHAPTER 9 *Digestion and Assimilation of Food*

Digestion. The stored materials are generally insoluble in water or cell-sap and also indiffusible, but when translocation is necessary they are rendered soluble and diffusible by the action of enzymes. It is only in the soluble forms that food materials are absorbed by the protoplasm. *This rendering of insoluble and complex food substances into soluble and simpler forms suitable for translocation through the plant body and assimilation by the protoplasm is collectively known as digestion.*

The process of digestion is chiefly intra-cellular, that is, it takes place inside the cell. Extra-cellular digestion occurs in a few cases, as in the digestion of proteins by carnivorous plants, parasites, fungi, etc. Digestion, like all other physiological functions, is performed by the protoplasm. For this purpose it secretes digestive agents known as **enzymes**.

Enzymes. Enzymes are digestive agents secreted by the protoplasm to act upon insoluble and complex foodstuff and other substances and render them soluble. They also act upon soluble materials and split them up into simpler compounds. They are very complex organic compounds (containing nitrogen) and are protein in nature. They are soluble in water,

and when dry, form a white amorphous powder. They are not directly formed by the protoplasm, but at first very minute granules, known as *zymogen*, are secreted by it. The zymogen is then converted into the active enzyme, e.g. pepsin from pepsinogen and trypsin from trypsinogen. Here pepsin and trypsin are the enzymes and pepsinogen and trypsinogen are the zymogens. A temperature of 70°C. destroys the properties of most enzymes.

Properties of Enzymes. (1) The action of an enzyme is mostly specific, i.e. for a particular substance there is a particular enzyme; for instance, the enzyme that acts on starch will not act on protein or any other substance. This is expressed as 'lock and key' action. (2) The enzyme is never exhausted; a small quantity of it can act on an almost unlimited supply of the substance, provided that the products of digestion are removed from the seat of its activity. (3) The enzyme acts as a catalytic agent; this means that the presence of the enzyme induces some chemical action in the substance without itself undergoing any change. Thus the enzyme may be regarded as an organic catalyst.

Kinds of Enzymes and Nature of Digestion

- 1 **Diastase** converts starch into dextrin and maltose.
- 2 **Maltase** converts maltose into glucose.
- 3 **Invertase** changes sucrose into glucose and fructose.
- 4 **Cellulase** converts cellulose into glucose.
- 5 **Cytase** converts hemicellulose into glucose.
- 6 **Inulase** changes inulin into fructose.
- 7 **Pepsin** changes proteins into peptones.
- 8 **Trypsin** transforms proteins into amino-acids.
- 9 **Erepsin** transforms peptones into amino-acids.
- 10 **Lipase** breaks up fats into fatty acids and glycerine.

Assimilation. Assimilation is the absorption of the simplest products of digestion of foodstuff by the protoplasm into its own body and conversion of these products into the similar complex constituents of the protoplasm (the term assimilate means to make similar.) The various kinds of carbohydrates are converted into sugar, particularly glucose, and the various kinds of proteins converted into peptones and amino-acids. These simplest products of digestion travel to the growing regions where the protoplasm is very active. Here glucose is mostly broken down during respiration, releasing energy;

while the digested products of proteins are assimilated by the protoplasm into its own body. We know that the protoplasm itself is a living substance composed of very complex proteins. The food proteins are, therefore, changed into complex protoplasmic proteins, i.e. into 'live' proteins, or, in other words, food passes from non-life into life, that is, protoplasm. This is the goal of nourishment. How this mysterious change takes place we do not know. We know only that the protoplasm has the power of bringing it about.

CHAPTER IO *Respiration*

Respiration is essentially a process of oxidation and decomposition of organic compounds, particularly simple carbohydrates, such as glucose, in the living cells with the release of energy. The most important feature of respiration is that by this oxidative process the potential energy stored in the organic compounds in living cells is released in a stepwise manner in the form of active or kinetic energy under the influence of a series of enzymes and is made available, partly at least, to the protoplasm for its manifold activities such as manufacture of food, growth, movements, reproduction, etc. Often a considerable amount of energy escapes from the plant body in the form of heat, as seen in germinating seeds. It is principally glucose that undergoes oxidation, but sometimes in its absence other materials like fats, proteins, organic acids and even protoplasm under extreme conditions may also be oxidized. The main facts associated with respiration are: (1) consumption of atmospheric oxygen, (2) oxidation and decomposition of a portion of the stored food resulting in a loss of dry weight as seen in the seeds germinating in the dark, (3) liberation of carbon dioxide and a small quantity of water (the volume of CO_2 liberated being equal to the volume of O_2 consumed), and above all (4) release of energy by the breakdown of organic food. The over-all chemical reaction may be stated thus: $\text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2 \rightarrow 6\text{CO}_2 + 6\text{H}_2\text{O} + \text{Energy}$ (sugar + oxygen \rightarrow carbon dioxide + water + energy). This shows that for oxidation of one molecule of sugar six molecules of oxygen are used and that six molecules each of CO_2 and H_2O are formed. By burning sugar at a high temperature CO_2 and H_2O are also formed, but in the living cells

this process is carried on by a series of enzymes at a comparatively low temperature.

All the living cells of the plant, however deeply seated they may be, must respire day and night in order to live. If the supply of air is cut off by growing the plant in an atmosphere devoid of oxygen, it soon dies. Growing organs, such as the floral and vegetative buds, the germinating seeds, and the stem- and root-tips, respire actively; while adult organs do so comparatively slowly. Entry of oxygen and exit of carbon dioxide normally take place through the stomata, and in shrubs and trees through lenticels also (see fig. 317). For diffusion of gases through the plant body a network of inter-cellular spaces and air-cavities develops in it.

Aerobic and Anaerobic Respiration (*aer*, air; *an*, not; *bios*, life). Normally free oxygen is used in respiration resulting in complete oxidation of stored food and formation of carbon dioxide and water as end products; this is known as aerobic respiration. A considerable amount of energy is released by this process as represented by the equation $C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O + 674$ cal. (sugar) + oxygen \rightarrow carbon dioxide + water + 674 cal. of energy). Under certain conditions, as in the absence of free oxygen, many tissues of higher plants, seeds in storage, fleshy fruits and succulent plants like cacti temporarily take to a kind of respiration, called **anaerobic respiration**, which results in incomplete oxidation of stored food and formation of carbon dioxide and ethyl alcohol, and sometimes also various organic acids such as malic, citric, oxalic, tartaric, etc. Very little energy is released by this process to maintain the activity of the protoplasm. This may be represented by the equation— $C_6H_{12}O_6 \rightarrow 2C_2H_5OH + 2CO_2 + 28$ cal. (sugar \rightarrow ethyl alcohol + carbon dioxide + 28 cal. of energy). It is otherwise known as *intramolecular respiration*. Anaerobic respiration may continue only for a limited period of time, at most a few days, after which death ensues. Certain bacteria and fungi normally take to anaerobic respiration for release of energy.

Experiment 14. Respiration (fig. 345). A flask with a bent bulb, called **respirometer** (or an ordinary long-necked flask) with some germinating seeds in it is inverted over a beaker containing a good quantity of mercury. A small caustic potash stick is introduced into the flask. The respirometer is fixed in a vertical position with a suitable stand and clamp. The enclosed air in the flask is completely cut off from the outside atmosphere. Now leave the apparatus in this position for some hours, preferably till the next day.

It will then be seen that mercury has risen in the flask to the extent of *nearly* one-fifth the total volume of the flask. The rise of the mercury is evidently due to absorption of a certain volume of gas contained in the flask. Since caustic potash absorbs carbon dioxide it may be easily inferred that the gas absorbed is carbon dioxide. This gas must have been exhaled by the germinating seeds during respiration.

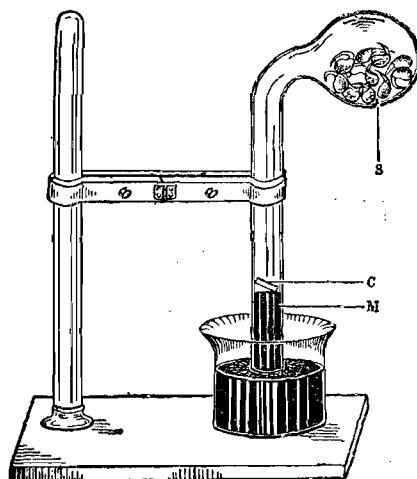

FIG. 345

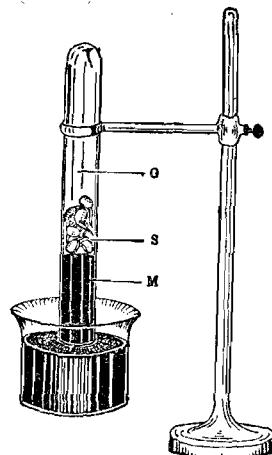

FIG. 346

Experiments on Respiration. FIG. 345. Aerobic respiration. FIG. 346. Anaerobic or intramolecular respiration. S, seeds; C, caustic potash stick; M, mercury; G, gas.

Note. Instead of mercury dilute caustic potash solution may be used. The rise of this solution in the flask will be one-fifth the total volume of the enclosed air. This indicates that the volume of carbon dioxide evolved is equal to the volume of oxygen absorbed since oxygen occupies one-fifth the total volume of air.

Experiment 15. Anaerobic respiration (fig. 346). Completely fill a short narrow test-tube with mercury (M), close it with the thumb and invert it over mercury contained in a beaker. Keep the tube in a vertical position with a suitable stand. Take some germinating seeds, and remove the seed-coat from them to get rid of the enclosed air (oxygen). With the help of the forceps hold the skinned seeds under the test-tube, and release them one after another. As soon as released the seeds rise to the closed end of the tube. Introduce in this way five or six seeds. They are now free from oxygen. Prior to their introduction it is better to soak the seeds in distilled water, or to introduce into the test-tube a small quantity of distilled water with the help of a bent tube. This keeps the seeds moist. Note on the following day that the mercury column has been pushed down, owing to the exhalation of a gas (G) by the seeds. Within one or two days nearly the whole of the mercury is seen to be pushed out of the tube. Introduce a small piece of caustic potash stick into the test-tube with the help of the forceps. It floats on mercury, and coming in contact with the

gas, absorbs it quickly. The mercury rises again and fills up the test-tube. The gas evidently is carbon dioxide.

Respiration is a destructive process consisting of the decomposition of some of the food materials, more particularly the simple carbohydrates, and this decomposition is brought about by the action of specific enzymes secreted by the protoplasm. Nevertheless, it is highly beneficial to the life of the plant for the reason that respiration sets free *energy* by which work is performed. This energy is absolutely necessary for the various synthetic processes, growth, movements, etc. If we think of the enormous development of a large tree we can at once realize what a vast amount of energy has been utilized in constructing that body. A considerable amount of energy, of course, escapes from the plant body in the form of heat. During vigorous respiration heat is generated. A thermometer thrust into a mass of germinating seeds will show a marked rise in temperature (see experiment 16). This production of heat is an easily observed form of energy. Respiration results in a loss of dry weight of the plant. This is believed to be due to the escape of carbon dioxide.

Experiment 16. Heat generated in respiration (fig. 347). Take two thermoflasks, and fill one of the (A) with germinating seeds and the other (B) with the seeds killed by boiling for a few minutes and then soaked in 5% formalin to prevent any fermentation in the flask generating heat. Insert a sensitive thermometer in each as shown in the figure and pack the mouth of the flask with cotton. It is better to place, half-immersed in seeds, a small test-tube containing a small piece of caustic potash stick. Wait for some time and note a remarkable rise in temperature in the case of flask A containing germinating seeds; while flask B containing killed seeds shows no rise of temperature. This evidently proves that heat is evolved in respiration.

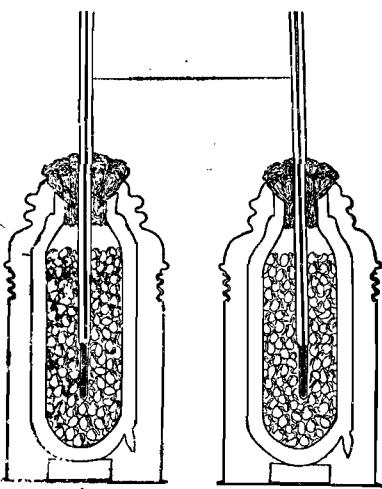

FIG. 347. Experiment to show that heat is generated in respiration.

Conditions affecting Respiration. (1) **Oxygen.** The presence of oxygen is the first and the most essential condition for respi-

ration since this is an *oxidation* process. If the concentration of oxygen in the air goes below 5 per cent the process rapidly falls off. With higher concentration up to even 100 per cent the rate correspondingly increases.

(2) **Temperature.** This affects markedly the rate of respiration. The minimum rate is reached at 0°C. or even at 10°C., and the maximum at 45°C. or even at 40°C. Beyond this point protoplasm is injured and respiration decreases in rate.

(3) **Light.** The effect of light is only indirect; in bright sunlight the respiratory activity is greater than in subdued light, possibly because the stomata remain wide open for free exchange of gases.

(4) **Supply of Water.** Protoplasm saturated with water respires more vigorously than protoplasm in a desiccated condition, as in the dry seed. For this reason the rate of respiration increases with the supply of water.

(5) **Vitality of Cells.** Respiration in young active cells is more rapid than in old cells. Vegetative buds, floral buds and germinating seeds respire more vigorously than older parts of the plant body.

(6) **Carbon Dioxide Concentration.** If, as a result of respiration, carbon dioxide be allowed to accumulate, respiration slows down and may even come to a standstill.

(7) **Nutritive Materials.** Soluble carbohydrate, more particularly glucose, affect respiration to a considerable extent since the latter is quickly broken down in the process releasing energy.

Respiration and Photosynthesis. (1) In respiration plants utilize oxygen and give out carbon dioxide, while in photosynthesis plants utilize carbon dioxide and give out oxygen; that is, one process is just the reverse of the other.

(2) Respiration is a destructive (catabolic) process, but photosynthesis is a constructive (anabolic) process. In the former process sugar is broken down into CO₂ and H₂O with the liberation of energy, while in the latter process CO₂ and H₂O are utilized to build up sugar with the storage of energy. Respiration is thus a *breaking-down* process, and photosynthesis a *building-up* process.

(3) The intermediate chemical reactions in the breakdown of sugar in respiration and those in the synthesis of sugar in photosynthesis are much the same. In both processes phos-

phoglyceric acid is formed representing an intermediate product.

(4) Respiration is performed by all the living cells of the plant at all times, i.e. it is independent of light and chlorophyll; while photosynthesis is performed only by the green cells, and that, too, only in the presence of sunlight. Although photosynthesis persists only for a limited period, this process is much more vigorous than respiration.

(5) Respiration results in a loss of dry weight of the plant due to breaking-down of food materials and the formation of carbon dioxide which escapes from the plant body; but photosynthesis results in a gain in dry weight due to formation of sugar, starch, etc., which accumulate in the plant body.

Fermentation is the incomplete oxidation of sugar into alcohol and carbon dioxide brought about by certain micro-organisms in the absence of oxygen. The change is due to the action of an enzyme, known as *zymase*, secreted by the micro-organisms, and not due to their direct action on sugar. Fermentation is most readily seen in date-palm juice, where sugar is broken up by unicellular yeast plants into alcohol and carbon dioxide, the frothing being due to the formation of this gas. The process is analogous to anaerobic respiration and may be represented by an identical formula— $C_6H_{12}O_6$ (sugar + zymase \rightarrow $2C_2H_5OH$ (alcohol) + $2CO_2$ (carbon dioxide) + zymase + energy.

CHAPTER II *Metabolism*

Two series of chemical changes or processes are simultaneously going on in a plant cell, one leading finally to the construction or building-up of the protoplasm, and the other to its decomposition or breaking-down. These processes, which are constructive on the one hand and destructive on the other, are together known as **metabolism**. Metabolism takes place only in the living cells, and is one of the characteristic signs of life. The processes that lead to the construction of various food materials and other organic compounds and finally of protoplasm are together known as **anabolism**, and those processes leading to their destruction or breaking-down as **catabolism**. The main anabolic or constructive changes are: formation of sugars and other carbohydrates, formation of

proteins, and formation of fats and oils. These changes or processes are regarded as anabolic because the protoplasm continually reconstructs itself with these nutritive substances. By anabolism a considerable amount of potential energy is stored in those substances for future use of the protoplasm. The main catabolic or destructive processes are: digestion, respiration and fermentation. By these processes complex food substances are gradually broken down into simpler products, e.g. various carbohydrates into glucose, various proteins into amines and amino-acids, and fats and oils into fatty acids and glycerine. The potential energy already stored up in them is released by catabolism into kinetic energy for manifold activities of the protoplasm. Carbon dioxide and water are formed as a result of complete oxidation of glucose in aerobic respiration, and alcohols and organic acids as a result of incomplete oxidation of glucose in anaerobic respiration or fermentation. Various secretory products such as enzymes, vitamins, hormones, cellulose, nectar, etc., and various waste-products such as tannins, essential oils, gums, resins, etc., are the results of catabolic processes.

B. PHYSIOLOGY OF GROWTH AND MOVEMENTS

CHAPTER 12 *Growth*

Growth is a vital phenomenon. The protoplasm assimilates the products of digestion and increases in bulk and weight. The cells divide and numerous new cells are formed; these increase in size and become fully turgid, and the plant grows as a whole. *Growth may be defined as a permanent and irreversible increase in size and form attended by an increase in weight.* Growth is usually very slow in plants, but it can be accurately measured with the help of an instrument, called the **arc indicator or lever-auxanometer** (fig. 348).

Experiment 17. Growth in Length of the Shoot. The **arc indicator** is an instrument by means of which a small increase in length can be magnified many times. From this total known magnification recorded by the instrument the actual length attained by a plant within a certain specified time can easily be calculated.

The arc indicator consists of a movable lever or indicator fixed to a wheel round which passes a cord, and a graduated arc. One end of the cord is tied round or gummed to the apex of the stem, and from the other end a small weight is suspended to keep the cord taut. As the stem increases in

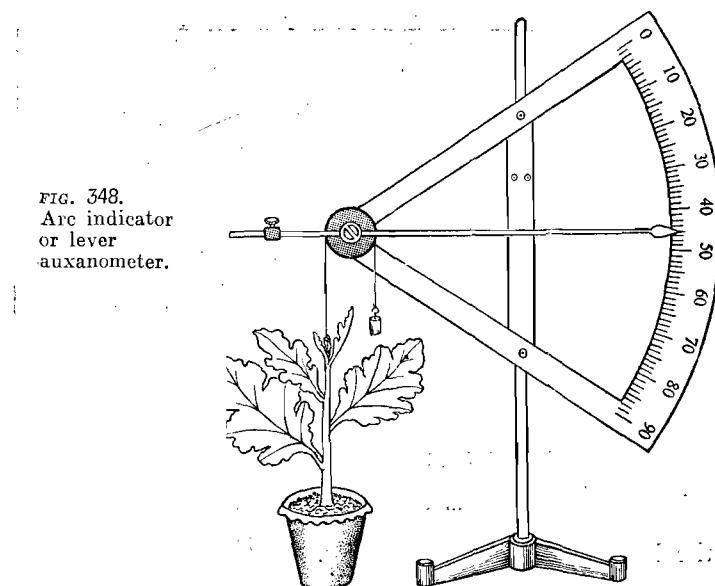

FIG. 348.
Arc indicator
or lever
auxanometer.

length the wheel slowly rotates under the suspended weight and the indicator moves down the graduated arc. The growth in length of the plant is thus recorded by the instrument on a magnified scale. From the record thus obtained the actual increase in length of the stem is calculated; for instance, if the lever has traversed a distance of 45 cm. in 24 hours, and the magnification is 90 times, the actual growth in the same period is $\frac{45}{90}$ cm., i.e., 0.5 cm. or 5 mm. and, therefore, in 1 hour the actual growth of the plant is $\frac{5}{24}$ mm., i.e. 0.2 mm.

Conditions necessary for Growth. Since growth is brought about by the protoplasm the conditions necessary for growth are the same as those that maintain the activity of the protoplasm (see p. 200). (1) A supply of **food** is indispensable for growth. It is the source of necessary nutritive materials required for growth and is also a source of energy to the protoplasm. (2) An adequate supply of **water** maintains the turgidity of the growing cells and the activity of the protoplasm. (3) A supply of **oxygen** is indispensable for respiration of all the living cells. Respiration releases *energy* stored in the food for the manifold activities of the protoplasm. (4) An average **temperature** of more or less $30^{\circ}\text{C}.$ is very suitable for protoplasmic activities and growth of the plant body. (5) The **force**

of gravity determines the direction of growth of certain organs, e.g. the root downwards towards this force, while the stem upwards away from it. (6) A certain intensity of **light** main-

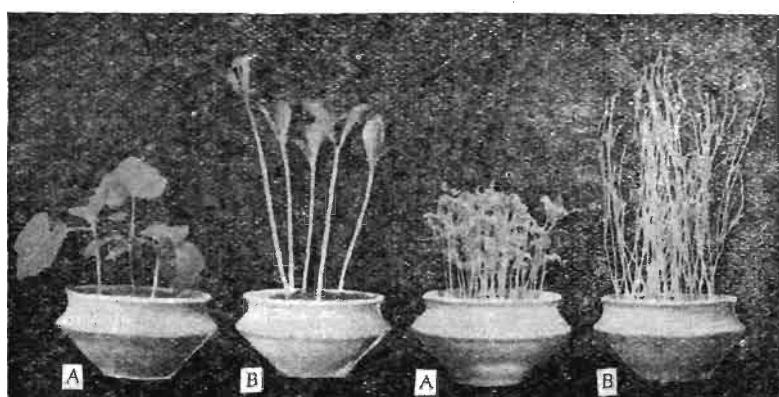

FIG. 349. Effect of light and darkness on the growth of seedlings. *Left*, gourd seedlings; *right*, gram seedlings. *A*, grown in light; *B*, grown in darkness.

tains the healthy condition of plants. Strong light, however, retards growth, as during the daytime, while continued absence of light makes plants soft, weak, brittle, slender, long and drawn out, pale-green or pale-yellow in colour and sickly in appearance; such plants are said to be **etiolated** (fig. 349). They seldom produce flowers. Moreover, stomata open and chloroplasts function only in the presence of light manufacturing food materials which are required for growth. The effect of unilateral light is discussed on p. 255.

Grand Period of Growth. Every organ of the plant body, in fact every cell that the organ is composed of, shows a variation in the rate of its growth. The growth is at first slow, then it accelerates until a maximum is attained, then it falls off rather quickly, and gradually slows down until it comes to a standstill. This growth of an organ or a cell or the plant as a whole extending over the whole period is called the **grand period of growth**. Within the grand period variations in growth occur owing to external and other causes. There is thus the *diurnal variation of growth*. Light inhibits growth, and too intense light even checks it altogether. Thus plants grow quicker during the night than during the day. During the night the retarding or inhibiting action of light is removed,

and the rate of growth of a plant gradually increases until dawn, while during the day the rate of growth gradually decreases until about sunset. There is also *seasonal variation of growth*; during winter the growth of many plants is checked or becomes very slow, but during spring growth proceeds rapidly.

Hormones. It is now definitely known that certain organic products formed in very minute quantities as a result of metabolism inside the plant body have a profound influence on the *growth* of the plant organs and on the various kinds of *tropic movements* exhibited by such organs; they also have a marked effect on certain physiological processes. They are known as the **hormones** or growth-regulating substances. They are formed in one part of the plant body, chiefly in the apical meristem, and transported from there to another part to produce a particular physiological effect there. The presence of hormones was first demonstrated by experimental methods. It has now been possible to extract them from plants by appropriate chemical methods. At low concentration they stimulate growth, while at high concentration they retard growth. Various kinds of hormones have been discovered till now. Of them auxins and heteroauxin (indole-acetic acid), first obtained from human urine, are well known. Certain synthetic compounds such as indolyl butyric acid also act as hormones. Heteroauxin causes the formation of roots in stem-cuttings, leaf-cuttings (fig. 350) and in grafting. Auxins are responsible for seed-germination, seedling-growth and growth of plant organs; they also stimulate cell divisions in the meristematic tissue, and influence certain physiological processes; also, the role of hormones in tropic responses has now been well established. Thus *phototropism* and *geotropism* are now explained on an hormonal basis. Hormones responsible for the development of the root, stem, leaf, flower, fruit, etc., have also been discovered.

Vitamins. Vitamins are a group of organic substances which have proved to be most valuable in preventing and curing deficiency diseases such as scurvy (livid spots on the skin and general debility), beri-beri, rickets, malnutrition, loss of appetite, poor physical growth, eye infection, nervous breakdown, etc., caused by the absence of vitamins in the food or their faulty absorption due to intestinal troubles. For over two centuries scurvy was a dreaded disease among sailors, resulting in many deaths. About the year 1793 it was found that the use of orange or lemon juice dispelled scurvy from the navy. Evidently the juice contains something (now known as vitamin C) which cures the disease. It was only from the year 1906 that investigations into vitamins were made from the biological standpoint and up to today several vitamins have been discovered and their value established.

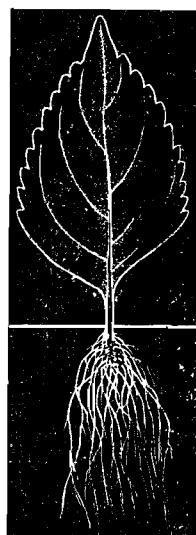

FIG. 350. Root-formation in leaf-cutting of *Pogostemon*, treated with indolyl butyric acid.

Vitamins are required only in minute quantities for a particular effect and they are used up in the metabolic processes. They are mostly formed by plants and stored up in their different organs. Plants are, therefore, the main sources of vitamins for animals including human beings. It has now been possible to synthesize some of the vitamins, particularly vitamins C and D, on a commercial scale. Some of the well-known vitamins are as follows.

Vitamin A is a growth-promoting vitamin, fairly resistant to heat. It increases resistance to bacterial infections of the lungs and the intestines, prevents many eye-diseases, particularly night-blindness, and cures skin-diseases and nervous weakness. Carotene of plants is the source of this vitamin, and animals can synthesize it in their bodies by taking food containing carotene of plants. Vitamin A is found in carrot, green leafy vegetables (spinach, lettuce, cabbage, etc.), cereals (particularly in their pericarp), pulses, many fruits (particularly yellow ones such as tomato, mango, orange, apple, papaw, etc.), fish-liver oils (e.g. cod-liver oil and halibut-liver oil), liver of mammals, milk, butter, egg-yolk, etc.

Vitamin B consists of a group of closely allied vitamins, commonly called *vitamin B complex*. Of these vitamin B₁ (soluble in water and not very resistant to heat) prevents beri-beri (accumulation of water in the body resulting in serious diseases). Beri-beri was for a long time a dreaded disease in the rice-eating countries of India, Malaya, China and Japan. Polished rice (evidently something removed from its pericarp, now known to be this vitamin) was found to be the cause of this disease which resulted in immense suffering and innumerable deaths. Other vitamins of this group are B₂, B₆, B₁₂, etc., each having its own function. Vitamin B complex is very widely distributed. One or more of them are found in dry yeast, cereals, pulses, most vegetables, many fruits (e.g. orange, banana, apple, tomato, etc.), nuts, milk, cheese, egg, meat, fish, liver, etc.

Vitamin C (soluble in water and sensitive to heat) prevents scurvy, mental depression, swelling and bleeding of gums, and degeneration of teeth. It is found in most fresh fruits (particularly orange, lemon, pummelo, tomato, pineapple, guava, papaw, etc.), many vegetables, sprouted pulses and cereals.

Vitamin D cannot stand strong light; otherwise it is sufficiently stable. Its deficiency causes rickets, softening of bones, dental caries, poor development of teeth, and inhibits proper absorption of calcium and phosphates. It is found in dry yeast, ergot, milk, butter, egg-yolk, fish and fish liver-oils. It is commonly associated with vitamin A. Vitamin D can be produced in the human body by the action of ultraviolet ray (from sunlight or electricity) on the skin.

Vitamin E is resistant to heat and light but destroyed by ultra-violet ray. Its deficiency causes sterility in animals (not yet definitely proved in the case of human beings) and degeneration of muscles. It is found in green vegetables, germinating grains, wheat embryo, etc.

To summarize, it may be said that our daily diet should include at least some of the following, as sources of vitamins, in addition to cereals and pulses : green vegetables, fruits including tomato, some of the vegetable oils, milk and milk products, eggs, animal liver, fish, meat, etc.

CHAPTER 13 *Movements*

Movement is a sign of life. But most plants are fixed to the ground and cannot move bodily. Protoplasm, however, is sensitive to various external factors which act as stimuli, such as heat, light, gravity, certain chemicals, electricity, etc., and many plant organs or entire free organisms respond to them by some kind of movement. The various kinds of movements may be broadly classified into (A) spontaneous or autonomic and (B) induced or paratonic.

A. **Spontaneous movement** is the movement of certain organs of plants or more commonly of entire free organisms *of their own accord*, i.e. without the influence of any external factor; it may be due to some internal cause not clearly understood. Common instances are: movements of protoplasm and all ciliate bodies, oscillating movement of *Oscillatoria* (see fig. 377), brisk movements of many desmids and diatoms, etc. Spontaneous movement of plant organs may be of two kinds, as follows:

(1) **Movement of variation** is the movement of *mature* organs due to *variation in turgidity* of the cells making up those organs. It is somewhat rapid, but instances are rather rare. The spontaneous movement of variation is, however, very remarkably exhibited by the *pulsation*, i.e. the rising and falling of the two lateral leaflets of the Indian telegraph plant (*Desmodium gyrans*; fig. 351) during the day-time, the terminal leaflet remaining fixed in its position.

(2) **Movement of growth** is the movement of growing organs *due to unequal growth* on different sides of those organs. It is very slow. This kind of movement is seen in some trailers and creepers. In them at one time the growth is comparatively rapid on one side of the stem and then it passes on to the opposite side. The stem tip then moves from one side to the other. In such a case the stem, as it elongates, moves in a zigzag course. Young fern leaves at first remain closely coiled but then because of more rapid growth

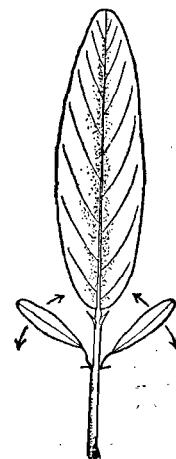

FIG. 351. Indian telegraph plant showing spontaneous movement of the two lateral leaflets.

on the upper side they uncoil and straighten out. Opening of flowers is also a kind of growth movement.

B. Induced movement is the movement of certain plant organs or of entire free organisms induced by some external factors acting as stimuli. The power of receiving stimulus from outside and of responding to it is spoken of as **irritability**. Irritability expresses itself in some kind of movement, depending on the nature of the stimulus. Induced movements may be of the following kinds: (a) taxes (*sing*, *taxis*), (b) tropisms and (c) nasties.

~~(a) Taxes~~ or **Taxic movements** are the movements of free organs or entire organisms induced by external stimuli such as light, temperature and chemical substances. Ciliate bodies like antherozoids and zoospores typically show taxic movement. These bodies are either attracted by the stimulus or are repelled by it.

~~(b) Tropisms~~ or **Tropic movements** are the movements of plant organs influenced by external stimuli, particularly contact, light, gravity and moisture. Tropic movement is always directive, i.e. the organ concerned moves either towards the source of the stimulus or away from it. Depending on the nature of the stimuli the movements may be as follows :

(1) **Haptotropism** is the movement of an organ induced by contact with a foreign body. Twining stems and tendrils are good examples of haptotropism. In such cases the reaction is rather slow and, therefore, the contact must be of long duration to bring about the movement. When such organs come in contact with any support or any hard object the growth of the contact side is checked, while the opposite side continues to grow. The result is that the organs slowly coil round that object. This is a mechanism for climbing. Some move clockwise and others anticlockwise. If the direction be artificially altered, growth becomes arrested.

(2) **Heliotropism** or **phototropism** is the movement of plant organs in response to incidence of rays of light. Some organs are attracted by unilateral light and grow towards it ; they are said to be *positively heliotropic*, e.g. the shoot ; and others grow away from it and are said to be *negatively heliotropic*, e.g. the root. Dorsiventral organs such as leaves, runners, etc., grow at right angles to the direction of light so that their upper surface is exposed to light ; such organs are said to be

diaheliotropic. Positive heliotropism is seen markedly in potted plants, particularly seedlings, when these are grown in a closed box (heliotropic chamber; fig. 352) with one open window on one side. They all tend to grow towards the window, i.e. towards the source of light, and ultimately come out through it. The flower-stalk of groundnut (fig. 353) grows towards light, but after pollination it becomes negatively heliotropic and positively geotropic like the root. The stalk bends down and quickly elongates, pushing the fertilized ovary into the ground where gradually the ovary ripens into a pod (fruit).

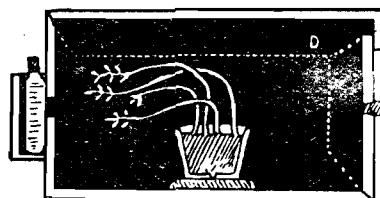

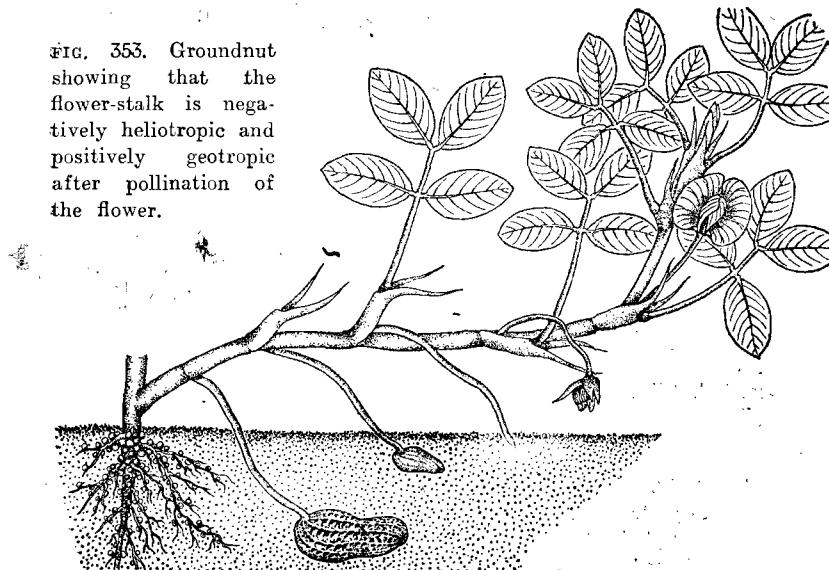

FIG. 352. Heliotropic chamber.

(3) **Geotropism** is the movement of plant organs in response to the force of gravity. Geotropism has a marked effect on the direction of growth of plant organs. The primary root is seen to grow towards the centre of gravity,

FIG. 353. Groundnut showing that the flower-stalk is negatively heliotropic and positively geotropic after pollination of the flower.

and the primary shoot away from it. The former is, therefore, said to be *positively geotropic*, and the latter *negatively*

geotropic. The lateral roots and the branches usually grow at right angles to the force of gravity and are said to be *diageotropic*. That the direction of growth is determined by the stimulating action of the force of gravity is clearly seen in a seedling which has been placed in a horizontal position away from light. Both the stem and the root undergo curvature in their growing region behind the apex, passing through an angle of 90° ; the root curves and grows vertically downwards, as does the stem upwards. It is the very tip of the root, for a distance of 1 to 2 mm. in length, that is sensitive to this stimulus; but the actual bending takes place some distance behind the tip in the region of greatest growth. If the tip of the root be decapitated, no bending takes place. Besides, it is seen that the root of a germinating seed can, under the force of gravity, grow downwards even through mercury overcoming considerable pressure. Further, it has been found possible with the help of a **clinostat** (fig. 354) to eliminate the effect of geotropic stimulus on the root and the shoot by introducing a centrifugal force (see experiment 18).

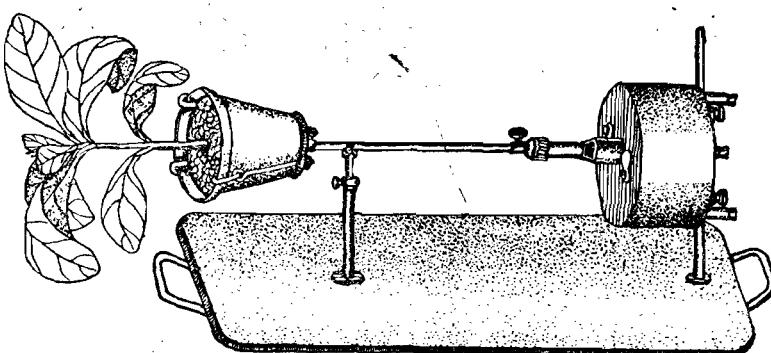

FIG. 354. Clinostat in the horizontal position to eliminate the effect of the force of gravity.

Experiment 18. Geotropism. A **clinostat** (fig. 354) may be used to demonstrate geotropism. A clinostat is an instrument by which the effect of lateral light and the force of gravity on an organ of a plant—root or stem—can be eliminated. It consists of a rod with a disc mounted on it, to which a small potted plant may be attached, and a clockwork mechanism for rotating the rod and the disc. The clinostat works slowly—its rotation being ordinarily $\frac{1}{4}$ to 4 turns per hour. A plant, preferably a pot plant, may be fixed in the clinostat in any position—vertical, horizontal or at an angle—and

made to rotate by clockwork mechanism in the clinostat. When the plant is horizontal, the root and the stem grow horizontally, instead of the root curving downwards and the stem upwards. This is due to the fact that all sides of the growing axes are in turn directed downwards, upwards and sideways so that the force of gravity cannot act on any definite position. This results in the effect of the force being eliminated altogether. The root and the stem cannot, therefore, bend. If, however, the plant be fixed in a vertical position and the clinostat rotated, it is seen that the plant grows in a vertical direction—the root downwards and the stem upwards.

(4) **Moisture.** The movement of an organ in response to the stimulus of moisture is known as **hydrotropism**. Roots are sensitive to variations in the amount of moisture. They show a tendency to grow towards the source of moisture, and are said to be *positively hydrotropic*. It is seen that roots of plants, growing in a hanging basket made of wire-netting and filled with moist sawdust, project downwards at first, coming out of the basket, under the influence of the force of moisture (moist sawdust of the basket), but turn back and pass again into the basket having formed loops.

Experiment 19. Hydrotropism. A porous clay funnel, covered around with a filter paper, is placed on a wide-mouthed glass bottle (or hyacinth glass) filled with water, as shown in fig. 355. The paper is thus kept moist. The porous funnel is filled with dry sawdust and the soaked seeds are arranged in a circle, each near a pore. It is necessary to add a few drops of water now and then to the seeds to help their germination. As they germinate it is seen that the roots, instead of going vertically downwards in response to the force of gravity, pass out through the pores towards the moist filter paper outside and grow downwards alongside the paper into the bottle. Roots thus show movements towards moisture, or, in other words, they are positively hydrotropic.

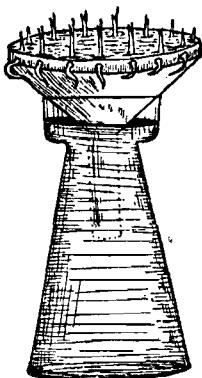

FIG. 355. Experiment on hydrotropism.

i.e. the direction of movement is not determined by the direction of the stimulus; in other words, whatever be the direction of the stimulus it equally affects all parts of the organs, and they always move in the same way and in the same direction. Two kinds of such movements are conspicuous, as follows.

(1) **Seismonasty** is the movement brought about by mechanical stimuli such as contact with a foreign body, poking with any hard object, drops of rain, a gust of wind, etc. Movements of the leaves (leaflets) of the sensitive plant (fig. 357), the sensitive wood-sorrel (*B. BAN-NARANGA*; *H.*

LAJALU—fig. 356), *Neptunia* (B. PANI-LAJUK), carambola (B. KAMRANGA; H. KAMRAKH), etc., are familiar examples. Leaflets of such plants close up, when touched. The Venus' fly-trap (*Dionaea*; see fig. 340) is another very interesting example.

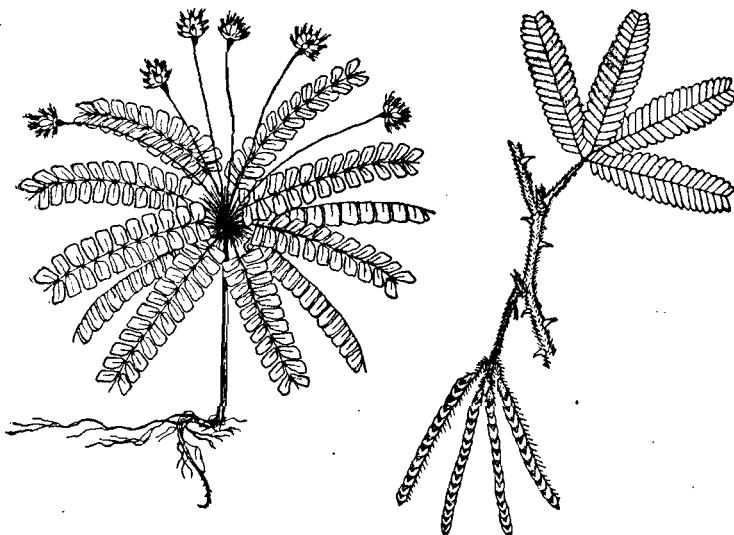

FIG. 356

FIG. 356. Sensitive wood-sorrel (*Biophytum sensitivum*).
FIG. 357. Sensitive plant (*Mimosa pudica*).

(2) **Nyctinasty** is the movement induced by alternation of day and night, i.e. light and darkness. It is otherwise called **sleep movement**. Leaves and flowers, particularly the former, are markedly affected by nyctinasty. This kind of movement is most remarkably exhibited by the leguminous plants. Leaflets of these plants close up and often the leaf as a whole droops in the evening when the light fails, and they open up again when the light appears in the morning. A few other plants like *Chenopodium* (B. & H. BATHUA-SAK), carambola (B. KAMRANGA; H. KAMRAKH), wood-sorrel, etc., also show the same phenomenon. Among the flowers showing nyctinasty mention may be made of *Gerbera* (a garden herb), *Portulaca* (wild or garden variety), etc.

C. PHYSIOLOGY OF REPRODUCTION

CHAPTER 14 *Reproduction*

Since the life of an individual plant is limited in duration it has developed certain methods by which it can reproduce itself in order to maintain the continuity of the species and also to multiply in number. The following are the principal methods of reproduction: **vegetative**, **asexual** and **sexual**.

I. VEGETATIVE REPRODUCTION

A. *Natural Methods of Propagation.* In any of these methods a portion gets detached from the body of the mother plant, and this detached portion embarks on a new career under suitable conditions, gradually growing up into a new independent plant.

(1) **Budding.** In the case of yeast (see fig. 278) one or more tiny outgrowths appear on one or more sides of the vegetative cell immersed in sugar solution. Soon these outgrowths get detached from the mother cell and form new individuals. This method of outgrowth-formation is known as budding. Often budding continues one after another so that chains and even sub-chains of cells are formed. The individual cells finally separate from one another and form new yeast plants.

(2) **Gemmae.** In *Marchantia*, special bodies, known as gemmae (see fig. 412), develop on the thallus for the purpose of vegetative propagation.

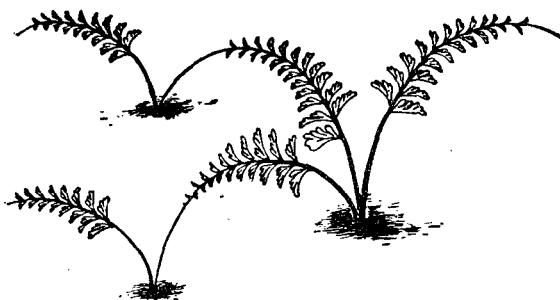

FIG. 358
Walking fern
(*Adiantum caudatum*).

(3) **Leaf-tip.** There are certain ferns, commonly called walking ferns (e.g. *Adiantum caudatum*), which propagate

vegetatively by their leaf-tips (fig. 358). As the leaf bows down and touches the ground the tip strikes roots and forms a bud. This bud grows into a new independent fern plant. Ferns normally, however, reproduce vegetatively by their rhizome.

(4) **Underground Stems.** Many flowering plants reproduce themselves by means of the rhizome, e.g. ginger, the tuber, e.g. potato, the bulb, e.g. onion, and the corm, e.g. *Gladiolus* and *Amorphophallus*. The buds produced on them gradually grow up into new plants.

(5) **Sub-aerial Stems.** The runner of wood-sorrel and Indian pennywort (fig. 359), the stolon of taro, the offset of water lettuce and the sucker of *Chrysanthemum* are made use of by such plants for vegetative propagation.

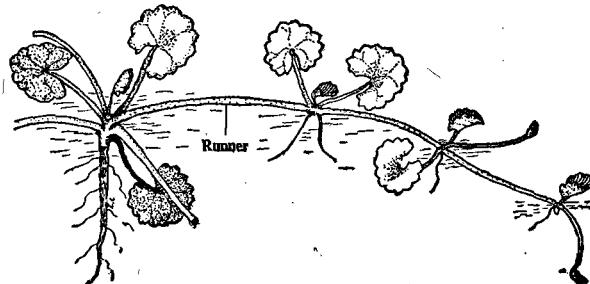

FIG. 359. Runner of Indian pennywort (*Centella*) showing vegetative mode of propagation.

(6) **Adventitious Buds.** In the sprout-leaf plant (*Bryophyllum pinnatum*; see fig. 60) and in *Kalanchoe* (fig. 360) a series of adventitious (foliar) buds are produced on the leaf-margin, each at the end of a vein; these buds grow up into new plants. In the elephant ear plant (*Begonia*; see fig. 61) a few

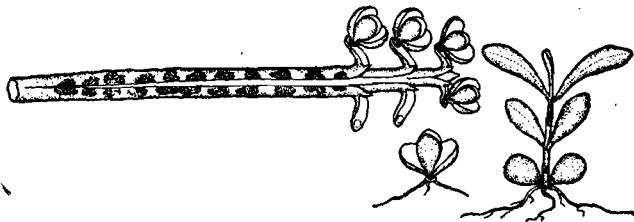

FIG. 360. A leaf of *Kalanchoe* sp. with adventitious buds.

adventitious buds are produced on the surface of the leaf from the veins and also from the petiole. Similarly the roots

of some plants may produce adventitious (radical) buds for the same purpose, as in sweet potato.

(7) **Bulbils.** In *Globba bulbifera* (fig. 361), American aloe (fig. 363) and garlic some of the lower flowers of the inflorescence become modified into small multicellular reproductive bodies called bulbils. These fall to the ground and grow up into new plants. Bulbils, big or small, are also produced in the leaf-axil of wild yam (*Dioscorea bulbifera*; B. CACHH-ALOO; H. ZAMINKHAND—wild yam (*Dioscorea bulbifera*); In wood-sorrel (fig. 364) a large number of small buds (bulbils)

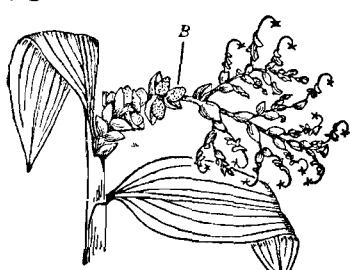

FIG. 361. *Globba bulbifera*.
B, bulbil.

may be seen on the top of the swollen tuberous root. These buds break off easily and grow up into new plants. In some

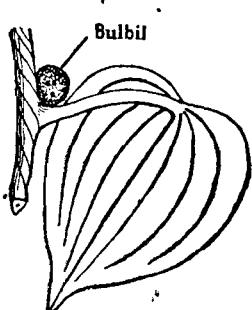

FIG. 362

Bulbils. FIG. 362. *Dioscorea bulbifera*. FIG. 363. Bulbil of American aloe (*Agave*). FIG. 364. Wood-sorrel (*Oxalis*).

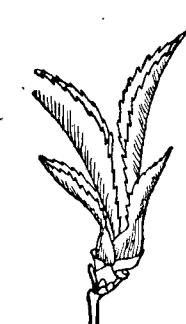

FIG. 363

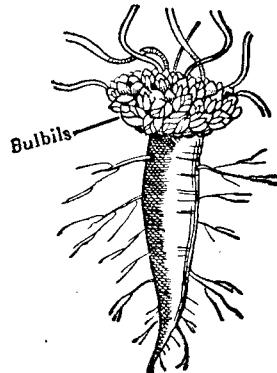

FIG. 364

varieties of pineapple (fig. 365) the inflorescence is surrounded at the base by a whorl of reproductive buds or bulbils and also crowned by a few of them.

B. Artificial Methods of Propagation. In any of these methods a portion can be separated from the body of the mother plant by a special method and grown independently. There are several such methods.

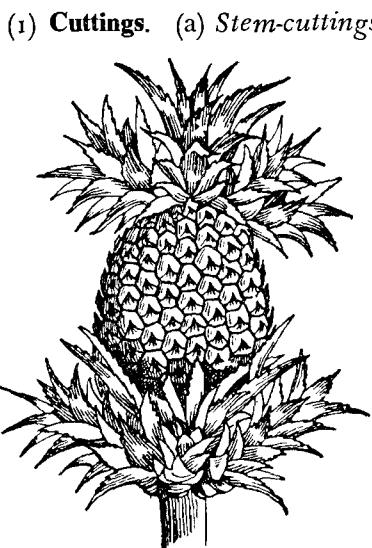

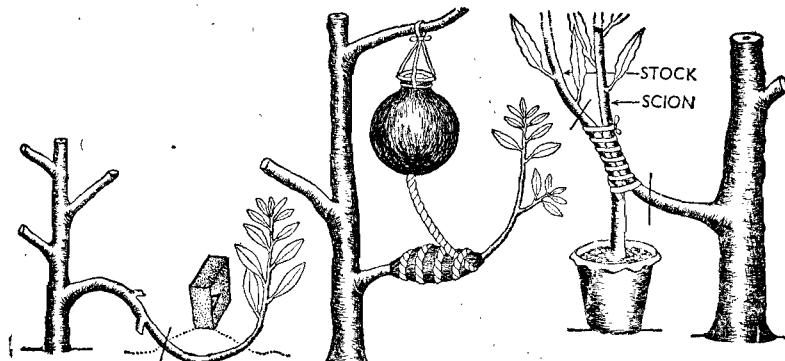

FIG. 365. Pineapple with a crown
and a whorl of bulbils.

including layering and gootee adopted for the sake of fruits,

(1) **Cuttings.** (a) *Stem-cuttings.* Many plants like rose, sugar-cane, tapioca, garden croton, China rose, drumstick (*Moringa*), *Duranta*, *Coleus* (see fig. 40), etc., may be grown easily from stem-cuttings. When cuttings from such plants are put into moist soil they strike roots at the base and develop adventitious buds which grow up. (b) *Root-cutting.* Sometimes, as in lemon, citron, ipecac (see fig. 53B), tamarind, etc., root-cuttings put into moist soil sprout, forming roots and shoots.

(2) **Grafting.** Some of the common methods of grafting

including layering and gootee adopted for the sake of fruits,

 FIG. 372. Crown grafting.

II. ASEXUAL REPRODUCTION

This takes place by means of special cells or asexual reproductive units, called spores, produced by the parent plant, which grow by themselves into new individuals, without two such cells fusing together, as in sexual reproduction. Spores are always unicellular and microscopic in size. They may be motile or non-motile.

(i) Motile spores are provided with one or more tail-like projections known as *cilia*. Such ciliate spores are called **zoospores**, as in many algae and fungi. Commonly they are formed

FIG. 373. Rejuvenescence in *Vaucheria*.

in large numbers and are very minute in size. After escaping from the mother plant they swim briskly about in water for

some time, clothe themselves with a wall losing their motility, and finally grow up into new plants. In *Vaucheria*, a green alga, the whole mass of protoplasm of a cell escapes as a single large zoospore (fig. 373) covered with many pairs of cilia. The zoospore swims freely in water for some time, clothes itself with a wall and develops into a new *Vaucheria* filament. This return of old protoplasm of a cell to a youthful condition again is known as **rejuvenescence**.

(2) Non-motile spores commonly borne by terrestrial fungi are very light and dry, and provided with a tough coat. Such spores are well adapted for dispersal by wind and at the same time to meet the ever-changing conditions of the atmosphere. They are of diverse kinds, and have received special names according to their mode of origin.

(3) True spores are always borne by a sporophyte. In mosses and ferns which show distinct alternation of generations reproduction takes place by both asexual and sexual methods. The sporophyte reproduces asexually by spores which on germination give rise to the gametophyte, and the gametophyte reproduces sexually by gametes which by fusion in pairs (male and female) give rise to the sporophyte again.

III. SEXUAL REPRODUCTION

This consists of the fusion of two sexual reproductive units, called **gametes**. Gametes are always unicellular and microscopic in size. Two gametes of opposite sexes fuse together. The product of such fusion is a new cell called the **zygote**; the zygote develops into a new plant.

(1) **Conjugation.** In lower algae and fungi the pairing gametes are essentially similar, i.e. not differentiated into male and female, and are called *isogametes*. The union of such similar gametes is known as **conjugation**, and the zygote thus formed is called the **zygospore**, as in *Ulothrix* (see fig. 381), *Spirogyra* (see figs. 384-5) and *Mucor* (see fig. 395.). In *Ulothrix* several small *motile* gametes are produced in a cell, while in *Spirogyra* and *Mucor* a single large *non-motile* gamete is produced in a cell.

(2) **Fertilization.** In all the higher forms of plant life, on the other hand, the pairing gametes are dissimilar, i.e. differentiated into male and female, and are called *heterogametes*. The union of dissimilar gametes is known as **fertilization**, and the zygote thus formed is called the **oospore**. In higher algae

and fungi, mosses, ferns and allied plants male gametes are very minute, *motile*, *ciliate* and *active*, and are known as **antherozoids** or **spermatozoids**. The female gamete in them is *stationary*, *non-ciliate* and *passive*, larger in size, and is known as the **egg-cell**, **ovum** or **oosphere**. The corresponding male and female reproductive units in the 'flowering' plants are the **two gametes** of the pollen-tube and the **ovum** or **egg-cell** of the embryo-sac within the ovule.

IV. SPECIAL MODE OF REPRODUCTION

Parthenogenesis. The development of the zygote from the egg-cell without the act of fertilization, as seen in many lower plants, e.g. *Spirogyra*, *Mucor*, and in many ferns, is known as **parthenogenesis**. In some species of 'flowering' plants the embryo also may develop by parthenogenesis, i.e. without fertilization. The development of the fruit from the ovary without the act of fertilization is called **parthenocarpy**. Parthenocarpic fruits are almost always seedless. Examples are found in certain varieties of banana, pineapple, guava, grapes, apple, pear, papaw, etc. Sometimes mere spraying with certain chemicals (growth-promoting substances) like naphthalene-acetic acid results in the setting of fruits without fertilization (induced parthenocarpy).

PART IV ECOLOGY

CHAPTER I *Preliminary Considerations*

Ecology (*oikos*, house ; *logos*, knowledge) deals with the relations between plants or a plant community, or animals or an animal community (as they exist in their habitats) and the various factors of their environment. It investigates the various structural and functional peculiarities that have appeared in response to the conditions prevailing in the locality (environment). Ecology, therefore, involves both morphology (external and internal) and physiology. It should also be noted that plants give food and shelter to animals ; while the effects of animals and human communities on plants are also manifold. A study of ecology necessarily includes both animals and plants, and also the interactions between them.

Environment. Environment includes all the factors that affect the form and growth not only of individual plants, but also of plant associations. Environmental factors may be **climatic**, **edaphic** and **biological**.

(1) **Climatic Factors.** These include all the conditions of the atmosphere such as temperature, light, water (rainfall), wind, humidity, etc.

(2) **Edaphic Factors : Soils.** Edaphic factors include the physical and chemical nature of the soil, the availability of water and air in it, its temperature, its acidity or alkalinity, etc.

(3) **Biological Factors.** These include the action of soil bacteria, algae, protozoa, earthworms and burrowing animals which alter the soil, often making it fertile ; the competition of neighbouring plants for food, water and sunlight; parasitic fungi and bacteria, parasitic phanerogams ; symbiosis ; and insects which help pollination and also damage plants.

CHAPTER 2 *Ecological Groups*

Although plants sometimes occur as isolated individuals, more commonly we find that they become adapted to the same environment and are associated together in groups. The groups may include different plant species, belonging to different

families, and differing in shape, size, form and relationship, but which live under the same climatic and edaphic conditions. Some of the common groups are as follows.

1. **Hydrophytes.** These are plants that grow in water or in very wet places. They may be submerged, partly submerged, floating, or amphibious. Their structural adaptations are mainly due to the high water content and the deficient supply of oxygen.

Adaptations. The main features of aquatic plants are the reduction of protective tissue (epidermis here is meant for absorption, and not for protection), supporting tissue (lack of sclerenchyma), conducting tissue (minimum development of vascular tissue) and absorbing tissue (roots mainly act as anchors, and root-hairs are lacking), and the special development of air-chambers for aeration of internal tissues.

The Root. The root system is on the whole feebly developed, and root-hairs and root-caps are absent. Some floating plants are rootless, e.g. bladderwort (see fig. 344) and hornwort; while others have a cluster of fibrous roots but no root-caps and root-hairs, e.g. water lettuce (see fig. 68), water hyacinth (see fig. 82) and duckweed (see fig. 39); in these, instead of the root-cap, an analogous structure called the root-pocket is formed (see p. 29). In those fixed to the ground under water, either submerged, e.g. *Vallisneria* (see fig. 204) and *Hydrilla*, or partly submerged with floating leaves, e.g. water lily and lotus, there is scanty development of the roots.

The Stem. This may be in the form of a rhizome, small or large, or it may be long and slender, either branched or unbranched. The stem and the branches, particularly the latter, are soft and spongy, containing a large number of air-cavities filled with gases (oxygen and carbon dioxide for respiration and photosynthesis). They also help the plants to keep in position under water or to float. There is minimum development of mechanical and vascular tissues. Xylem and phloem are reduced to a few narrow vessels and sieve-tubes respectively. The epidermis is without cuticle and is meant for absorption of water. There may be some chloroplasts in it. In some plants prickles are present for self-defence.

The Leaf. Leaves of submerged plants are thin and generally ribbon-shaped, finely dissected or linear, rarely broad. Cuticle and stomata are absent. The epidermis contains some chloroplasts so that it can utilize the weak light under water

for photosynthesis. It is, however, primarily meant for absorption of water. The mesophyll is not differentiated into palisade and spongy tissues. Leaves of floating plants are well developed, and have a thick cuticle and a large number of stomata on the upper surface. Exchange of gases takes place

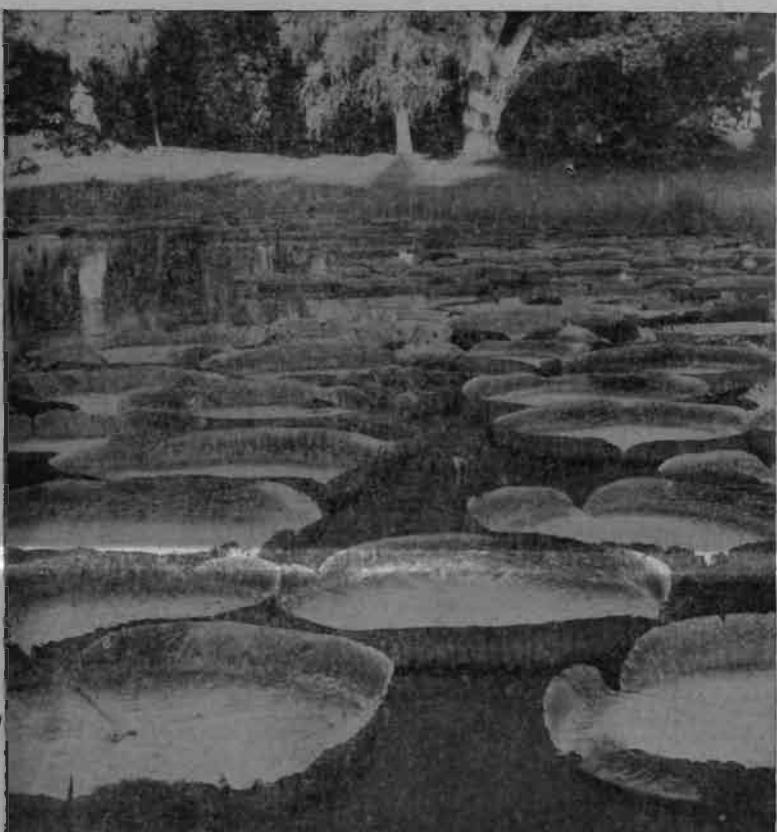

FIG. 374. Giant water lily (*Victoria regia*). Photograph taken at the Indian Botanical Gardens, Calcutta.

through the upper surface, and absorption of water through the lower. Many air-cavities develop in them and also in the petiole for the purpose of aeration and necessary buoyancy. Amphibious plants subjected to alternate flooding and drying often show **heterophyly** (*heteros*, different; *phylla*, leaves), i.e. they bear different kinds of leaves on the same individual (see pp. 69-70).

Examples. (a) **Submerged** : *Vallisneria* (see fig. 204), *Hydrilla*, *Naias*, etc. (b) **Floating** : bladderwort (see fig. 344), hornwort, duckweed (see fig. 39), water lettuce (see fig. 68), water hyacinth (see fig. 82), water chesnut (see fig. 58), etc. (c) **Partly submerged** : water lily, lotus, *Euryale* (B. & H. MAKHNA), giant water lily (fig. 374) etc. (d) **Amphibious** (showing heterophyly) : water crowfoot, water plantain, arrowhead (see fig. 135), *Cardennera triflora* (see fig. 132), etc.

2. **Mesophytes.** These are plants that grow under average conditions of temperature and moisture ; the soil in which they grow is neither saline nor is it waterlogged, and the temperature of the air is neither too high nor too low. Mesophytes are, therefore, intermediate between hydrophytes and xerophytes.

Adaptations. The root-system is well-developed with the tap root and its branches in dicotyledons, and a cluster of fibrous roots in monocotyledons ; root-hairs are luxuriantly produced for the absorption of water from the soil. The stem is solid (and not spongy, as in water plants), erect, and normally branched. Thorns on the stem are absent or few. All the different kinds of tissues, particularly the mechanical and conducting tissues, have reached their full development in the mesophytes. The aerial parts of plants such as the leaves and the branches are provided with a cuticle. In dorsiventral leaves the lower epidermis is provided with numerous stomata ; there are few stomata or none at all on the upper surface. In erect leaves, as in monocotyledons, stomata are more or less equally distributed on both surfaces.

3. **Xerophytes.** These are plants that grow in deserts or in very dry places ; they can withstand a prolonged period of drought uninjured. For this purpose they have certain peculiar adaptations. Dominant factors in a desert or a very dry region are : scarcity of moisture in the soil and extreme atmospheric conditions, such as intense light, high temperature, strong wind and aridity of air.

Adaptations. In such conditions the xerophytic plants have to guard against excessive evaporation of water ; this they do by reducing evaporating surfaces. They have also to adopt special mechanisms for absorbing moisture from the soil and retaining it.

The Root. Plants produce a long tap root which goes deep into the sub-soil in search of moisture ; many of the desert

plants which live for a short period produce a superficial root-system to absorb moisture from the surface-soil after a passing shower of rain. To retain this water roots often become very fleshy and contain plenty of mucilage, as in *Asparagus*.

The Stem. Stems of many plants become very thick and fleshy, as in Indian aloe (*Aloe*) and American aloe or the century plant (*Agave*). Aqueous tissue develops in them for storing up water ; this is further facilitated by the abundance of mucilage contained in them. Stems are provided with thick cuticle to prevent loss of water by transpiration. In many cases the stem becomes reduced in size and is provided with thorns, as in *Euphorbia spinosa*. Modification of the stem into phylloclade for storing water and food and at the same time performing functions of leaves is characteristic of many desert plants, e.g. cacti (see fig. 74A).

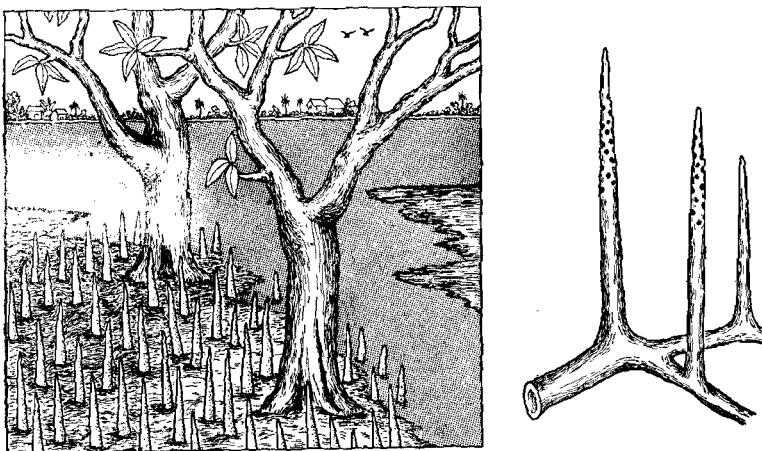

The Leaf. In some desert plants leaves are very fleshy, containing aqueous tissue and mucilage, as in Indian aloe ; in others they are reduced in size minimizing their evaporating surfaces. Thus they may be divided into small segments, as in *Acacia*, or modified into spines, as in many cacti and spurge (*Euphorbia*), or sometimes reduced to small scales only, as in *Tamarix* and *Asparagus*. The cuticle develops strongly on the epidermis to check evaporation of water. For the same purpose sometimes multiple (many-layered) epidermis develops, as in oleander (see fig. 301 B). In some plants, as in *Gnaphalium* and *Aerua*, there is a dense coating of hairs. Stomata are fewer in number—usually 10-15 per sq. mm., and remain sunken in grooves and occluded (see figs. 301 A & B). Modification of the leaf into phyllode, turning its edge in a vertical direction in strong sunlight to minimize transpiration, is characteristic of Australian *Acacia* (see fig. 119). Under conditions of extreme dryness leaves of most xerophytic grasses and also of many other plants roll up, considerably reducing their evaporating surfaces. Many of the xerophytic herbs lie prostrate on the ground, completing their life-history within a short time, e.g. *Solanum xanthocarpum* and *Tribulus terrestris* ; some are perennial in habit. Many xerophytes are elaborately armed with prickles and spines.

Examples. Many spurge (*Euphorbia*), many cacti, dagger plant (*Yucca* ; see fig. 136), Indian aloe, American aloe, prickly poppy, globe thistle, *Asparagus*, gum tree (*Acacia*), *Tribulus*

terrestris (B. GOKHRI-KANTA; H. GOKHRU), *Solanum xanthocarpum* (B. KANTIKARI; H. KATELI) and some grasses.

4. **Halophytes.** These are plants that grow in saline soil or water with a preponderance of salt; hence halophytes show some special characteristics. The majority of halophytes have succulent leaves; some have a succulent stem also. Leaves may be modified into or provided with spines. Typical examples of halophytes are sea-blite, saltwort, screwpine (see fig. 55), *Acanthus ilicifolius* (B. HARGOZA; H. HARKUCH-KANTA), goosefoot (*Chenopodium*; B. & H. BATHU-SAK), *Basella* (B. PUIN; H. POI), etc.

Special Adaptations. Halophytes growing on sea-coasts and estuaries, and also in salt-marshes and salt-lakes occasionally

A
Pneumatophores. FIG. 375. A, two plants with pneumatophores; B, pneumatophores growing vertically upwards from an underground root.

inundated by sea tides, form a special vegetation known as **mangrove**. Mangrove plants produce a large number of **stilt roots** (see fig. 55) from the main stem and the branches. In several cases, in addition to the stilt roots, special roots called **respiratory roots** or **pneumatophores** (figs. 375) are also produced in large numbers. They develop from underground roots, and projecting beyond the water level look like so many conical spikes distributed all round the trunk of the tree. In some places they grow so thickly that passage through them is difficult. They are provided with numerous pores or respiratory spaces in the upper part, through which exchange of gases

for respiration takes place. Mangrove species also show a peculiar mode of germination.

The seed germinates inside the fruit while it is still on the parent tree and is nourished by it. This kind of germination is known as **vivipary** (fig. 376). The radicle elongates to a certain length and swells at the lower part. As the seedling drops, the root presses into the soft mud, keeping the plumule and cotyledons clear above the saline water. Lateral roots are quickly formed for proper anchorage. The advantage is that the fruit cannot be swept away by tidal waves. Typical mangrove plants are *Rhizophora*

(B. KHAMO), *Ceriops* (B. GORAN), *Sonneratia* (B. KEORA), *Heritiera* (B. SUNDRI), *Excoecaria* (B. GEO), etc.

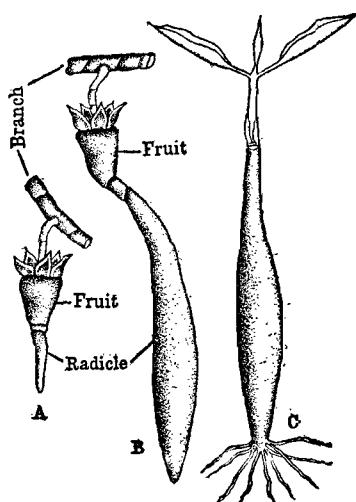

FIG. 376. Viviparous germination.

PART V CRYPTOGAMS

CHAPTER I *Divisions and General Description*

Cryptogams are plants that do not bear flowers or seeds and hence are commonly known as 'flowerless' or 'seedless' plants. They are broadly classified as follows (see also item 12 in Introduction) :

(1) **Thallophyta.** The plant body is a thallus, i.e. not differentiated into stem and leaf. Thallophyta include (a) **algae**, i.e. thallophytes containing chlorophyll and sometimes also other pigments, (b) **fungi**, i.e. thallophytes without chlorophyll, and (c) **bacteria**, i.e. unicellular, microscopic, non-green (without chlorophyll) organisms.

(2) **Bryophyta.** The plant body is thalloid or leafy ; there is regular alternation of generations ; the main body is always a gametophyte ; the sporophyte always grows attached to the gametophyte as a dependent body. Bryophyta include (a) **liverworts**, i.e. bryophytes with mostly thalloid plant body, e.g. *Riccia* and *Marchantia*, and (b) **mosses**, i.e. bryophytes with leafy stem.

(3) **Pteridophyta.** The plant body is differentiated into the stem, leaves and roots ; there is regular alternation of generations ; the sporophyte and gametophyte are independent of each other ; the main plant is always a sporophyte ; vascular tissues are well developed (another name for Pteridophyta is *vascular cryptogams*). Pteridophyta include ferns and their allies.

• Thallophyta are primitive plants and are regarded as lower cryptogams, while Bryophyta and Pteridophyta are advanced plants and are regarded as higher cryptogams.

Reproduction. Of the three methods of reproduction, viz., vegetative, asexual and sexual, a particular plant may take to one or more methods. Vegetative reproduction takes place commonly by cell division or by fragmentation. Asexual reproduction takes place by fission or by spores of varied types in different groups of plants. Sexual reproduction takes place

by the fusion of two gametes—either isogametes, as in lower forms, or heterogametes, as in higher forms (see p. 264).

Differences between Algae and Fungi. (1) Algae are green thallophytes containing the green colouring matter *chlorophyll*. In many algae the green colour may be masked by other colours ; fungi, on the other hand, are non-green thallophytes having no chlorophyll in them. (2) Algae are *autotrophic* plants, i.e. they manufacture their own food with the help of chlorophyll contained in them ; whereas fungi are *heterotrophic*, i.e. their modes of nutrition are diverse ; they may get their food from decaying animal or vegetable matter, or from the tissue of a living plant or animal ; accordingly they are either saprophytic or parasitic in habit. (3) The body of the algae is composed of a *true parenchymatous tissue* ; while that of the fungi is composed of a *false tissue* or pseudo-parenchyma which is an interwoven mass of fine delicate threads known as *hyphae*. (4) The cell-wall of an alga is composed of true cellulose, and that of a fungus of fungus-cellulose or chitin mixed with cellulose, callose, pectose, etc., in different proportions. (5) Algae live in water or in wet substrata ; whereas fungi live as parasites on other plants or animals or as saprophytes on decaying animal or vegetable matter. (6) Reserve carbohydrate in algae is usually starch, but in fungi it is glycogen.

In structure both the groups may be unicellular, multicellular, filamentous or thalloid, and reproduction in them may take place vegetatively by cell division or by detachment of a portion of the mother plant, or asexually by spores, or sexually by gametes.

Alternation of Generations. The life-history of any of the higher cryptogams, e.g. liverworts, mosses and ferns, is complete in two stages or generations, alternating with each other. These two generations differ not only in their morphological characters but also in their modes of reproduction. One generation reproduces by the asexual method, i.e. by spores, and the other by the sexual method, i.e. by gametes. The former, therefore, is called the **sporophytic** or asexual generation, and the latter the **gametophytic** or sexual generation. To complete the life-history of a particular plant one generation gives rise to the other—the gametophyte to the sporophyte and the sporophyte to the gametophyte, or in other words,

the two generations regularly alternate with each other. This alternation of the gametophyte with the sporophyte and vice versa is spoken of as alternation of generations.

Cytological Evidence of Alternation of Generations. Alternation of generations can be traced on the basis of chromosome numbers. It is an established fact that the sporophyte bears diploid or $2n$ chromosomes, while the gametophyte bears haploid or n chromosomes. The diploid number of the former is reduced (by meiosis) to the haploid number of the latter in the formation of spores (n). The spore gives rise to the gametophyte, evidently representing the beginning of the gametophytic generation. In due course the gametophyte bears gametes. Two gametes of opposite sexes (by fusion) give rise to the zygote ($2n$). The zygote grows into the sporophyte, evidently representing the beginning of the sporophytic generation. The sequence of stages in the two generations briefly is: zygote → sporophyte → spore mother cells (stages representing sporophytic or $2n$ generation) → spores → gametophyte → gametes (stages representing gametophytic or n generation).

CHAPTER 2 *Algae*

I. OSCILLATORIA (100 sp.)

Oscillatoria (fig. 377) is a dark blue-green alga. It consists of a slender, unbranched, cylindrical filament (A). It commonly

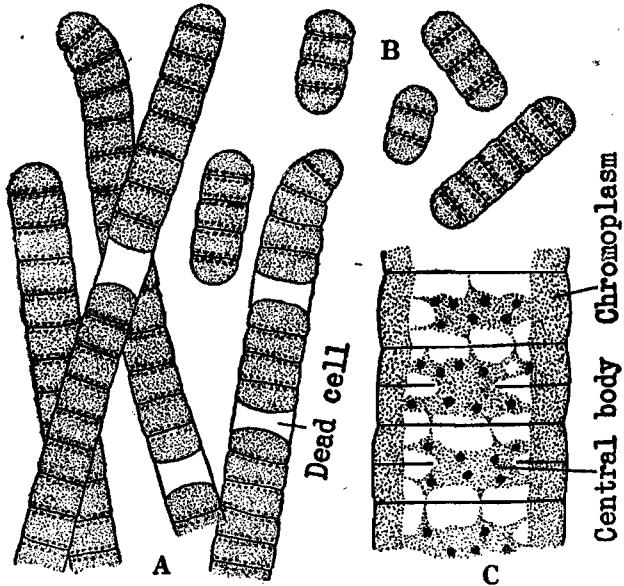

FIG. 377. *Oscillatoria*. A, filaments; B, hormogonia; and C, a portion of the filament magnified.

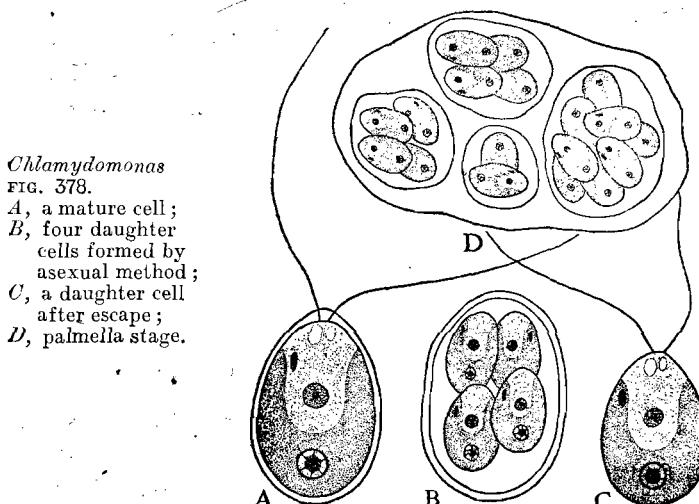

occurs in ditches, sewers, shallow pools of water and also on wet rocks and walls. Filaments of *Oscillatoria* are entangled in masses which float in water. Each filament is made up of numerous short cells. The individual cells are the *Oscillatoria* plants, and the filament is regarded as a colony. All the cells are alike except the end cell which is usually convex, and there is no differentiation between the base and the apex. Here and there some dead and empty cells occur in some of the filaments. The protoplasm of each cell is differentiated into two regions: a coloured peripheral zone—the **chromoplasm** and an inner colourless zone—the **central body** (C). The colour is due to the presence of chlorophyll and phycocyanin (a blue pigment) which diffuse through the chromoplasm. There is no plastid. True nucleus is also absent. The central body, however, is regarded as an incipient nucleus with only some chromatin but without nuclear membrane and nucleolus. Cell division takes place in one direction only. Each filament remains enveloped in a thin mucilaginous sheath. Under the microscope a slow swaying or oscillating movement of the filaments with ends tossing from side to side may be distinctly seen. The filaments may sometimes exhibit a twisting or rotating motion. This is a characteristic feature of *Oscillatoria*.

Reproduction. In blue-green algae reproduction takes place vegetatively. Gametes and zoospores are altogether absent. In *Oscillatoria* the filament breaks up into a number of fragments, called **hormogonia** (B). Each hormogonium consists of one or more cells and grows into a filament by cell divisions in one direction. The hormogonium has a capacity for locomotion.

2. *CHLAMYDOMONAS* (43 sp.)

Chlamydomonas is a unicellular green alga found in ponds, ditches and other pools of stagnant water. In shape it is usually spherical or oval, and is provided with a thin wall and two distinct long cilia (fig. 378 A). The protoplasm at the anterior end of the cell is clear, and contains two contractile vacuoles which are pulsating in nature, undergoing alternate expansion and contraction. These may be respiratory or excretory in function. There is a lateral orange or red pigment spot, commonly called the *eye spot*. This is sensitive

to intensity of light. In the posterior region there is a single large cup-shaped chloroplast with a pyrenoid in it. The pyrenoid consists of a central protein body surrounded by numerous minute starch grains. There is a nucleus more or less centrally placed. By the lashing of the cilia the cells quickly move about in water.

Chlamydomonas

FIG. 378.

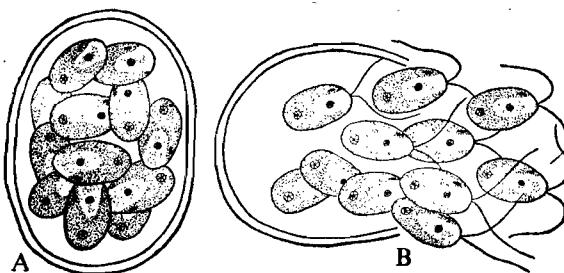

- A, a mature cell;
- B, four daughter cells formed by asexual method;
- C, a daughter cell after escape;
- D, palmella stage.

Asexual Reproduction. This takes place by zoospores. In the formation of the zoospores the cilia of each cell are withdrawn, and the contents divide into 2, 4 or 8 daughter cells, seldom more (fig. 378 B). The cells grow, develop two cilia each, and become motile zoospores. The wall of the mother cell dissolves and the zoospores are set free (fig. 378 C).

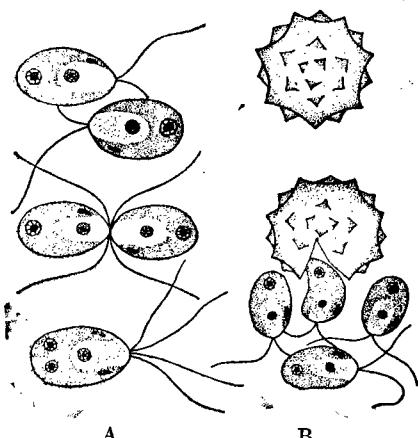

Palmella Stage. Under unfavourable conditions the daughter cells instead of forming zoospores divide repeatedly into numerous cells. Their walls become gelatinous, and the cells are held together in clusters in the gelatinous mass. This is known as the palmella stage (fig. 378 D). When the conditions are favourable the cells develop cilia, swim out of the gelatinous matrix, and become motile again.

Sexual Reproduction. This takes place by the fusion of motile ciliate gametes which are formed in the same way as the zoospores and are also like them but somewhat smaller in size and more numerous—16, 32 or 64, or even more (fig. 379 A-B). All gametes are similar and are called *isogametes*, and their fusion is known as *isogamy*. Gametes of different

parents usually conjugate in pairs (fig. 380 A). A **zygospore**—the product of fusion of two similar gametes—is formed. Their ciliate ends conjugate first. Soon after fusion the cilia

are withdrawn and the zygospore clothes itself with a thick wall (fig. 380 B, *top*). It undergoes a period of rest, and then its contents divide and form 2 or 4 motile daughter cells (fig. 380 B, *bottom*). They grow in size, escape from the mother cell, and become individual motile *Chlamydomonas* cells.

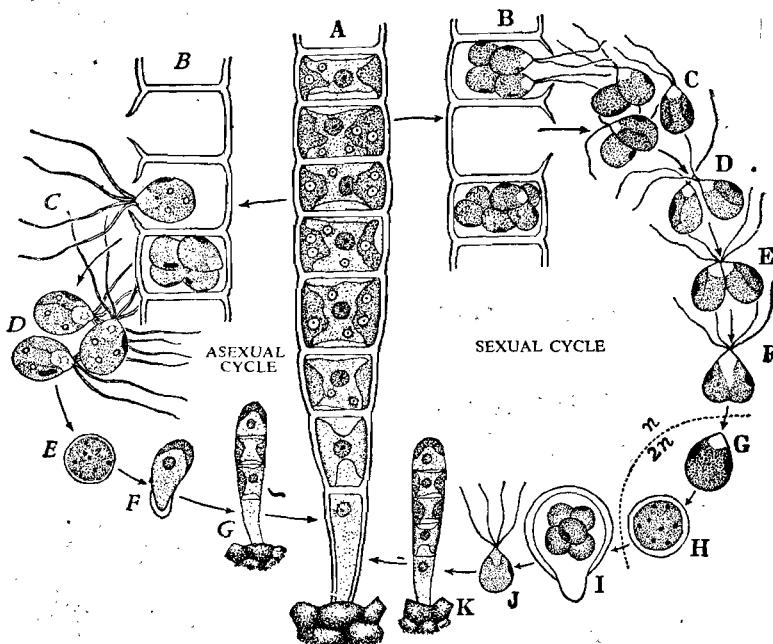

3. *ULOTHRIX* (30 sp.)

Ulothrix (fig. 381) is a green filamentous alga occurring in fresh water in ponds, ditches, water-reservoirs, horse- or cow-troughs, slow streams, etc., particularly in the spring ; a few species are marine. It grows fixed to any hard object in water by the basal elongated colourless cell called the *holdfast*. The filament, if detached, may freely float on water. The filament of *Ulothrix* is unbranched and consists of a single row of more or less rectangular cells. Each cell of the filament contains a

nucleus and a peripheral band-like chloroplast with an entire or lobed margin. Usually there are many (sometimes one or few) *pyrenoids* lying embedded in the chloroplast. These are rounded protein bodies with a starchy envelope.

Reproduction takes place asexually by zoospores, sexually by gametes, and vegetatively by fragmentation of the filament.

Asexual Reproduction. (1) Zoospores with four cilia are produced for the process of asexual reproduction by division of the protoplast of any cell of the filament except the holdfast. They are larger than the gametes but produced in fewer numbers—2, 4, or 8 or sometimes even 1, (rarely 16 or 32)

Ulothrix. FIG. 381. Life-cycle: **sexual reproduction**—A, vegetative filament; B, formation of gametes; C, gametes swimming; D-G, stages in the conjugation of gametes; H, zygospore; I, the germ-plant with zoospores; J, a zoospore (quadriciliate); K, a young filament; **asexual reproduction**—B, a portion of the filament showing the formation of zoospores; C, a quadriciliate zoospore; D, zoospores swimming; E, a zoospore rounded off; F, zoospore germinating; and G, a young filament.

in each cell. Each zoospore is more or less pear-shaped and contains a distinct red *eye spot* on one side, a pulsating vacuole close to the flagellate end, and a large chloroplast. The zoospores escape by an opening in the lateral wall of the cell and

swim briskly about in water for some hours or even for a few days. Then they come to rest and attach themselves by their colourless end to any hard object in water. Cilia are withdrawn and a cell-wall is formed round each zoospore. Then it germinates directly into a new filament. (2) Sometimes smaller zoospores (but bigger than gametes) are produced in the filament, and they possess either two cilia or four cilia. They either germinate directly into new *Ulothrix* filaments like the zoospores, or they fuse in pairs like the gametes. This indicates that the origin of gametes lies in zoospores.

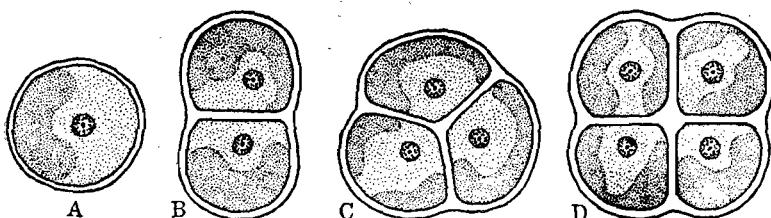

Sexual Reproduction. Sexual reproduction is isogamous, consisting of the fusion of two similar biciliate gametes (*isogametes*). The gametes may be formed in any cell of the filament except the holdfast. They are smaller than the zoospores, biciliate and may be 8, 16, 32 or 64 in number in each cell. Each gamete possesses a red *eye spot* and a chloroplast band. The gametes are set free from the cell in exactly the same way as the zoospores and they swim about in water with the help of their cilia for some time. Two gametes coming from two different filaments get entangled by their cilia and gradually a complete fusion (conjugation) of the two takes place laterally. Cilia are withdrawn towards the close of the process, and the fusion product still moves for a while but soon comes to rest. It rounds itself off and clothes itself with a thick cell-wall, and forms into a **zygospore**. After a period of rest the zygospore germinates into a unicellular *germ-plant* which produces 4 to 16 quadriciliate zoospores. Each zoospore develops into a new plant.

Vegetative Reproduction. This takes place by **fragmentation** of the filament into short pieces, each consisting of a few cells. Each piece or fragment grows into a long filament by transverse divisions of cells and their enlargement.

4. *PROTOCOCCUS* (14 sp.)

Protococcus (or *Pleurococcus*) is a common unicellular green alga. It is terrestrial in habit and grows on moist shady sides of tree-trunks, old damp bricks, brick-walls, flower-pots, etc., forming a green covering. Each plant is commonly represented by a single globose or oval cell. But as a result of division of the solitary cell 2, 3, 4 or more cells may appear in a small group or colony. Ciliate cells and gelatinous covering are conspicuous by their absence, and so also are gametes and zoospores. Under conditions of excessive moisture *Protococcus* cell may divide in one direction forming a short filament consisting usually of 3 or 4 cells, sometimes many more. Each cell is filled with a dense mass of cytoplasm and covered by a rather heavy

wall. It encloses a single nucleus and a large parietal chloroplast without any pyrenoid.

Protococcus. FIG. 382. *A*, a single cell; *B-D*, small colonies formed by divisions of the cell.

Reproduction. The only method of reproduction is vegetative cell division which is often rapid. In this process a transverse wall appears across the cell, and a second wall may then be formed in one or both the daughter cells at right angles to the first wall. Subsequent walls, if formed, are in the third plane. The daughter cells may remain attached together in small groups or they may separate and form independent cells (plants). The cells have the remarkable power of resisting desiccation. They begin to divide again under favourable conditions.

5. *SPIROGYRA* (100 sp.).

Occurrence. *Spirogyra* (fig. 383) is a green free-floating filamentous alga. It is found growing abundantly in ponds, ditches, springs, slow-running streams, etc.

Structure. Each *Spirogyra* filament is unbranched and consists of a single row of cylindrical cells. The walls are made of cellulose and pectin. Pectin swells in water into a gelatinous sheath. The filament shows no differentiation into the base and the apex. Each cell has a lining layer of protoplasm, one or more (up to 14) *spiral bands* of chloroplasts with smooth, wavy or serrated margins, and a distinct nucleus situated somewhere in the middle. The *spiral* chloroplasts are the characteristic feature of *Spirogyra*. Each chloroplast includes in its body a number of nodular protoplasmic bodies, known as *pyrenoids*, around which minute starch grains are

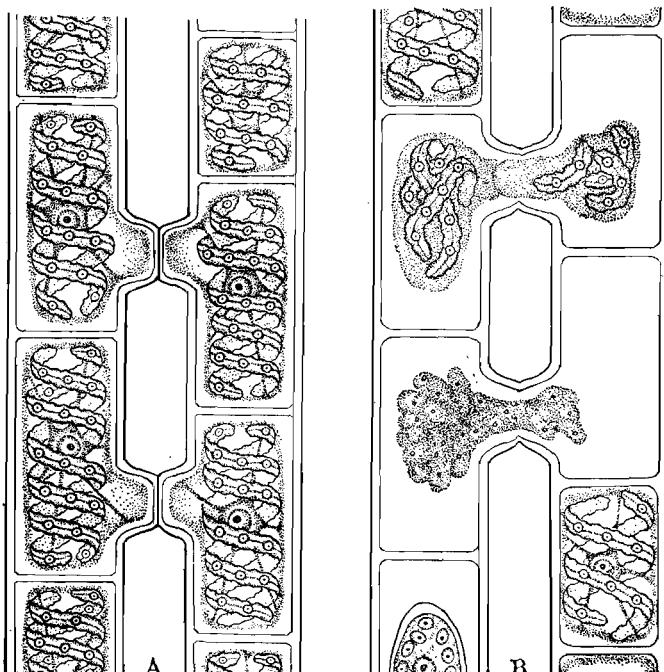

Spirogyra. FIG. 383.
A cell of the filament.
Note the two spiral
chloroplasts with pyre-
noids, and the nucleus.

deposited. If the filament happens to break up into pieces, they grow up into new filaments by cell divisions.

Reproduction. This takes place in *Spirogyra* by the sexual method only. It consists of the fusion of two similar gametes (isogametes). The fusion of two similar gametes is known as conjugation, which normally takes place between the cells of two filaments (scalariform or ladder-like conjugation ; fig. 384). Sometimes, however, conjugation takes place between two adjoining cells of the same filament (lateral conjugation ; fig. 386).

Scalariform Conjugation (fig. 384). When two filaments come to lie in contact in the parallel direction they form tubular

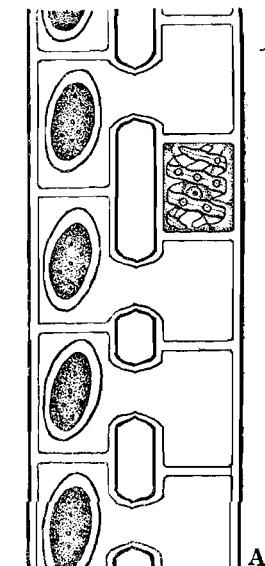

Spirogyra. FIG. 384. Scalariform conjugation. A-B are stages in the process.

outgrowths from their opposite or corresponding cells. These tubular outgrowths, called **conjugation tubes**, give the whole structure the appearance of a ladder (fig. 384 A) and hence the name scalariform or ladder-like conjugation. Their end- or partition-walls dissolve and an open conjugation tube is formed (fig. 384 B). In the meantime the protoplasmic contents of

each cell lose water, contract and become rounded off in the centre. Every contracted mass of protoplasm forms a **gamete**. All gametes are alike in appearance, but gametes of one filament (male) creep through the conjugation tubes into the corresponding cells of the adjoining filament (female) and fuse with the gametes of that filament. The fusion of two gametes results in the formation of a thick-walled **zygospore** (fig. 385) which soon turns black or brownish-black. Zygospores are formed in a series in one filament (female), while the other filament (male) becomes practically empty except for a few vegetative cells here and there.

Lateral Conjugation (fig. 386). This takes place between the cells of the same filament. An outgrowth or conjugation tube is formed on one side of the partition wall,

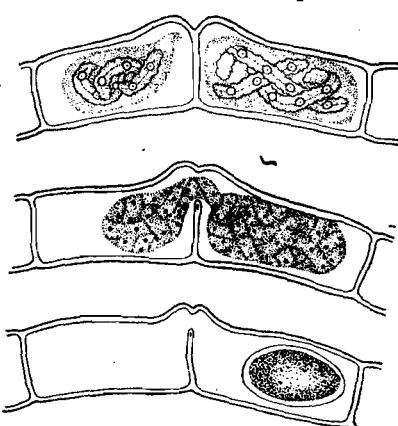

Spirogyra. FIG. 385. Formation of zygospores after conjugation.

and through the passage, thus formed, the gamete of one cell passes into the neighbouring cell. Sometimes only an opening is formed in the partition wall through which the gamete passes. In lateral conjugation the gametes of alternate cells only move to the neighbouring cells, and thus later on the zygote-bearing cells are seen to alternate with the empty cells in the same filament.

Sometimes it so happens that conjugation does not take place, and then a gametangium may become directly converted

into a zygospore-like body called the **azygospore**. It germinates like the zygospore.

Germination of the Zygospore (fig. 387). The zygospore is

Spirogyra. FIG. 386. Lateral conjugation and formation of zygospore.

provided with a thick cellulose-wall. It sinks to the bottom of the pool of water in which it is growing, undergoes a period of rest and then germinates. The protoplast of the zygospore grows out into a short filament which escapes and floats to the surface of the water. Cells divide and the filament increases in length.

Spirogyra. FIG. 387.
Zygospore germinating.

a single large peripheral chloroplast which takes the form of a network. Pyrenoids are present in the chloroplast.

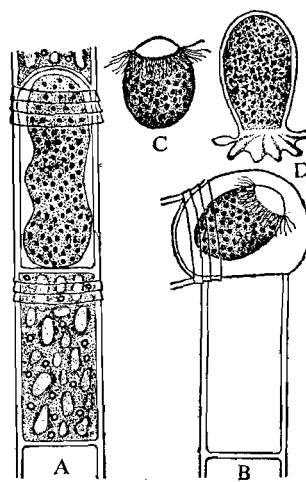

Asexual Reproduction (fig. 388B-D). This takes place by large zoospores formed singly in the cells of the filament. The whole contents of a cell become converted into a large zoospore.

The process is called **rejuvenescence** which means that the old protoplasmic mass of a cell rejuvenates, i.e. it becomes young and active again in the form of a zoospore (B). The zoospore is pear-shaped. One end of it is clear and with a ring of cilia, while the other (broader) end is green having a large chloroplast. The zoospore escapes from the mother cell and swims in water for a while (C). All the cilia are then withdrawn and a cell-wall formed round it. Soon it becomes attached to an object (D) and germinates, giving rise to a filament.

Sexual Reproduction (fig. 389). This takes place by the fusion of two differentiated gametes—the male one, called the **antherozoid**, is very minute, ciliate and motile, while the female one, called the **egg-cell** or oosphere, is large and passive. The antherozoids are borne in pairs in a cell called the **antheridium** (fig. 389A), and the egg-cell is borne singly in a large oval or spherical cell called the **oogonium** (fig. 389B). The antheridia are commonly formed in a row in any cell of the filament, while

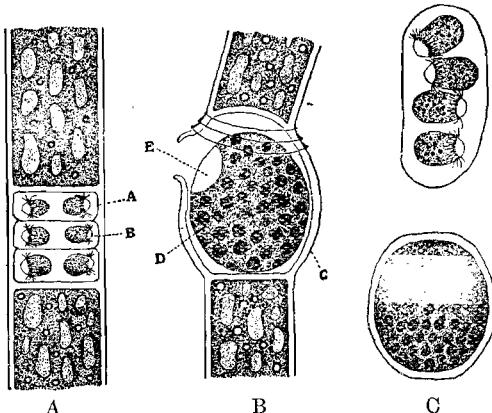

6. *OEDOGONIUM* (300 sp.)

Oedogonium (fig. 388A) is a green filamentous alga living in fresh water. The filament is unbranched, and consists of a row of cylindrical cells. It remains attached to an object by its lobed basal cell (*holdfast*), but later it may be free-floating. Each cell contains a single nucleus and

Oedogonium. FIG. 388. Asexual Reproduction. A, a filament showing a chloroplast and a zoospore in the process of formation; B, zoospore escaping; C, zoospore swimming; D, zoospore attached to an object.

the oogonia appear singly here and there in the filament. Species of *Oedogonium* may be monoecious or dioecious.

Oedogonium.

C, (bottom) an oospore;

(top) formation of

zoospores from it.

Fertilization. When the antherozoids are liberated they swim to the oogonium with the help of their cilia. Then one antherozoid enters through the slit in the oogonium wall and fuses with the egg-cell (fig. 389 B). The egg-cell then covers itself with a thick wall and becomes a reddish-brown **oospore** (fig. 389 C, bottom). The oospore sinks to the bottom, undergoes a period of rest and then germinates. By reduction division it gives rise to

Oedogonium. FIG. 390.

attached to it.

four **zoospores** (fig. 389 C, top). The zoospores escape and swim about for some time. Then they rest for a while, attach themselves to some object, and each germinates into a new filament.

In some species of *Oedogonium* a complicated process of reproduction takes place. In them special small zoospores, called **androspores** (fig. 390A), are produced by the same filament that bears the oogonia or by a distinct filament. Androspores are produced singly in special cells, called

androsporangia, which may be formed either singly or in a row like the antheridia by division of the ordinary vegetative cells of the filament. The androspore, much like the antherozoid and the zoospore, is provided with a crown of cilia and is motile. The androspore is, however, intermediate in size between the zoospore and the antherozoid. When liberated, the androspore swims for a while and soon attaches itself direct to the oogonium or to a cell close to it. It then produces a short narrow filament, called a **dwarf male** (fig. 390B), consisting of an elongated basal cell and a terminal cell or sometimes a row of cells (usually 2 to 4). Each such cell is an antheridium. It bears a pair of small motile antherozoids crowned with cilia. The antheridium opens by a lid at the apex or it ruptures at the wall and the antherozoids are liberated. They swim to the oogonium and fertilization takes place in the way described above.

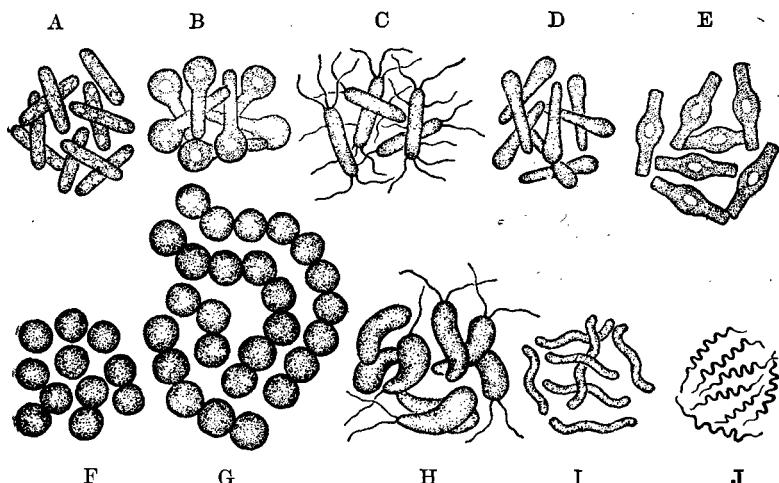

CHAPTER 3 *Bacteria (Schizomycetes)*

A Short Historical Account. Antoni von Leeuwenhoek (1632-1723) of Delft in Holland was the first to discover bacteria (1653-1673) with the help of the microscope invented and considerably improved by himself (see also p. 128). Louis Pasteur (1831-1895) of France thoroughly established the science of bacteriology. He carried on extensive work on fermentation and decay, and the cause of hydrophobia. About the year 1876 Pasteur made known to the world the importance of bacteria. He was the first to prepare vaccine and use it for the cure of the disease. He saved many Russians from hydrophobia by the use of this vaccine, and the Tsar of Russia in honour of his marvellous discovery sent him a diamond cross and also a hundred thousand francs to build a laboratory in Paris—now called the Pasteur Institute. About the same year Robert Koch of Germany proved that anthrax disease, so common in cattle, was caused by a kind of bacteria. He also showed in 1882 that tuberculosis and Asiatic cholera were caused by bacteria.

Occurrence. Bacteria occur almost everywhere—in water, air and soil, and in foodstuffs, fruits and vegetables. Many float in the air; many are abundant in water; and many are specially abundant in the soil, particularly to a depth of half a metre, and also in sewage. A few thousands of them may occur in 1 c.c. of water, and a few millions in 1 gram of soil. Many live within and upon the bodies of living plants and animals. The intestines of all animals always contain a good number of different kinds of bacteria.

Structure. **Bacteria** are the smallest and the most primitive organisms known to us, and number about 1,500 species. They are single-celled—usually spherical, rod-like or branched. Their average size may be stated to be .5 to 2 microns. There is no definite nucleus in the bacterial cell; chromatin granules repre-

senting an incipient nucleus are, however, present. The cell-

wall is made of chitin. Some forms of bacteria are provided with 1 or more cilia. Chlorophyll is altogether absent.

Reproduction. There is no sexual mode of reproduction in bacteria. They may divide repeatedly by fission or they may take to spore formation.

(1) *By Fission.* Many bacteria divide by the process of fission. A constriction appears around the middle of the cell and it becomes split up into two parts. These parts grow in size and form mature bacterial cells. By this method they

may multiply rapidly. Hay bacillus (*Bacillus subtilis*), for instance, divides 2 to 3 times an hour under favourable conditions. At the minimum rate of division a single cell may give rise to over sixteen million (16,777,216) offspring at the end of twelve hours.

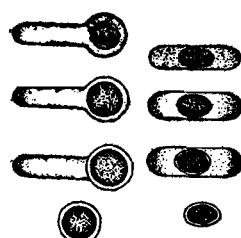

FIG. 391 (contd.). K-L, spore formation in two types of bacteria.

(2) *By Spore Formation* (fig. 391 K-L). Some bacteria form spores which are always 'resting' spores. The special advantage of the spores is that they

can withstand very unfavourable conditions such as high

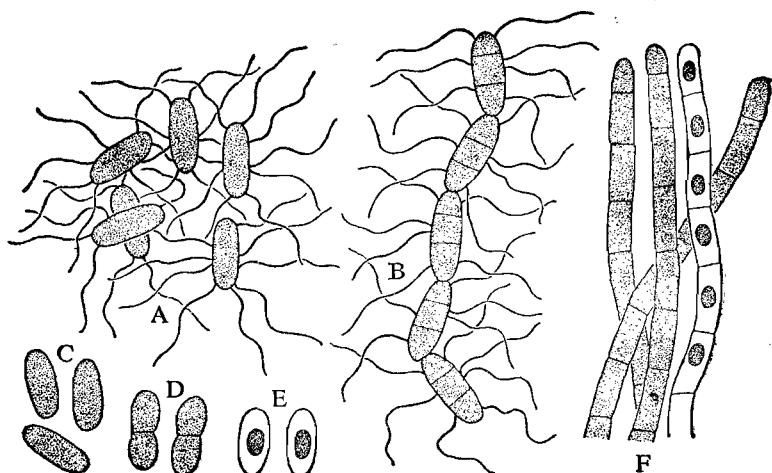

temperature, freezing, extreme dryness, the presence of many poisonous chemicals, etc., for months or even several years. By this method bacteria, however, do not multiply in number.

Classification. Unbranched unicellular forms of bacteria may be classified into the following groups: (1) **bacilli** (sing. *bacillus*)—these are rod-shaped bacteria, e.g. *Bacillus tuberculosis*, *B. tetani*, *B. typhi*, etc.; (2) **cocci** (sing. *coccus*)—these are spherical bacteria, e.g. *Staphylococcus*, *Streptococcus*, *Azotobacter*, etc.; (3) **spirilla** (sing. *spirillum*)—these are bacteria with the body spirally wound, e.g. *Spirillum*, *Spirochaete*, etc.; and (4) **commas**—these are slightly twisted like a comma, e.g. *Vibrio cholerae*.

Physiology of Bacteria. Bacteria are lacking in chlorophyll and thus are mostly unable to utilize carbon dioxide for synthesis of organic compounds for their food. They are mostly *heterotrophic* in habit, leading a saprophytic or parasitic life. A few, however, are *autotrophic* containing a purplish or greenish pigment, and are able to manufacture food for themselves. Saprophytic bacteria live in media containing some organic food. They secrete enzymes to bring about the digestion of carbohydrates, proteins and fats, and absorb the digested products as their food. Parasitic bacteria infect living plants and animals, and absorb food compounds from their body by the same process of enzyme-secretion and digestion.

Hay bacillus (*Bacillus subtilis*) is a common form of saprophytic bacteria growing in a decoction of hay. It can be grown easily in the laboratory by soaking hay in water and boiling it; the spores of hay bacillus withstand prolonged boiling. The decoction may then be kept in a warm place for a day or two. One or two drops of it may then be examined under a microscope at high magnification. Hay bacillus is unicellular and rod-shaped, provided with a number of flagella all over its body. The cells may be held together in chains. There is a granular vacuolated mass of protoplasm with chromatin granules but no definite nucleus. While growing in the fluid hay bacillus reproduces by fission. The cell undergoes constriction in the transverse plane and is split up into two. The process of fission may be repeated several times and numerous cells formed within a short time. It is seen that the cells overcrowding the liquid tend to come to the surface. The cells lose their cilia and become non-motile. Their walls become gelatinous and the cells are held together in long chains. Several such chains form a mucilaginous mass, called a *zoogloea*, which floats as a thin film or scum on the surface of the liquid. When food is exhausted, the bacillus cells form 1 or 2 spores, called *endospores*, within the mother cell. The protoplasm withdraws from the wall and clothes itself with a fresh firm wall which can resist the action of high temperature and many poisonous sub-

stances. Later under favourable conditions the spore germinates in a suitable medium. The wall of the mother cell decays and the spore is liberated. The tough coat of the spore splits and the protoplasm escapes into the

Hay bacillus (*Bacillus subtilis*). FIG. 392. A, motile forms; B, a chain of motile forms; C, non-motile forms; D, fission; E, spore formation; and F, chains of non-motile forms with spore formation in one chain.

surrounding water. Cilia are formed and the bacillus cell leads an active life.

Harmful Effects of Bacteria. Many parasitic (or pathogenic) bacteria attack living plants, human beings and domestic animals, and cause various and often serious diseases in them, sometimes in epidemic form. They are always dreaded as an invisible enemy. Normally they infect the host through wounds or they may be breathed in or taken in with food, water and milk. After infection of the body they not only absorb the stored food and destroy the cells but also at the same time produce a toxin (poison). Some of the common disease-producing bacteria are: *Bacillus typhi* causing typhoid fever, *B. tetani* causing tetanus, *B. diphtheriae* causing diphtheria, *B. pneumoniae* causing pneumonia, *B. tuberculosis* causing tuberculosis, *B. dysenteriae* causing dysentery, *Vibrio cholerae* causing cholera, etc. Some species of streptococci (the blood-poisoning bacteria) are possibly the deadliest enemy of mankind. They have the remarkable power of dissolving the red corpuscles of the human blood, and are responsible for erysipelas and extremely dangerous kinds of blood-poisoning.

Parasitic bacteria also attack plants and cause various

diseases such as blight disease of apple and pear, ring disease of potato, wilt of cucumber and melon, black rot of cabbage, canker of *Citrus*, and many diseases of fruits and vegetables. In plants, however, fungal diseases are far more common than bacterial diseases, while in animals the reverse is the case.

Many of the bacteria are also responsible for the decay (fermentation) of cooked food, meat, milk, vegetables, and fruits, etc., particularly in storage during summer months, often entailing heavy loss.

Beneficial Effects of Bacteria. Although some bacteria (the disease-producing ones) are most harmful it is a fact that a large number of them are most useful in various ways, particularly in agriculture and some industries. Many bacteria are nature's scavengers.

(1) **Agricultural.** (a) **Decay of Organic Substances.** But for the most useful work of many bacteria the dead bodies of plants and animals would remain unaltered covering a vast area. Besides, organic compounds contained in such dead bodies would remain permanently locked up in them without any further use. Fortunately, bacteria act on these bodies and convert various organic compounds into simple forms such as nitrates, sulphates, phosphates, etc. for utilization by green plants again. (b) **Nitrification.** Proteins contained in the dead bodies of plants and animals are acted on by different kinds of bacteria and ultimately converted into nitrates which are then absorbed and utilized by the green plants (see p. 210). (c) **Nitrogen Fixation.** Fixation of free nitrogen of the air by many soil bacteria like *Azotobacter* and *Clostridium* directly in their own bodies, and *Rhizobium* (nodule bacteria) in association with the roots of leguminous plants is very important from an agricultural standpoint. (d) **Fertility of the Soil.** The fertility of the soil may largely be attributed to the activity of soil bacteria (and also other soil organisms). They bring about physical and chemical changes in the soil, particularly conversion of insoluble materials into soluble and suitable forms for absorption by green plants. Thus they make the soil fertile. In addition, the conversion of cowdung and animal excreta into manure, and the formation of humus or leaf-mould are due to bacterial activity.

(2) **Industrial.** From an industrial standpoint also many bacteria are most useful. Curing and ripening of tobacco

leaves, fermentation of tea leaves, ripening of cheese, etc., for their characteristic flavours, retting of fibres, formation of vinegar from alcohol by acetic acid bacteria, fermentation of sugar into alcohol by yeast and a few bacteria, curdling of milk by lactic acid bacteria, conversion of hide into leather, and such other cases of fermentation are specially important.

(3) **Medical.** We are normally protected against virulent germs by many of the good bacteria which have been living as permanent flora in different parts of our body since our childhood. Thus different and distinct types of such bacteria have formed their permanent abode in the mouth, respiratory tract, intestines, etc., and guard these passages against invasion by the disease-producing germs by waging chemical warfare against them.

Viruses. There are still smaller organisms than the bacteria, which cannot be detected even under the most powerful microscope; these are the viruses. Their presence can be made out from the toxic effect they produce in the plant body or the animal body. Recent investigations have shown that viruses are the smallest, simplest and possibly the most primitive living organisms yet known to science. They infect living animals and plants, grow and multiply in them. Electron microscopes and X-ray photographs have further revealed the fact that a virus contains a core of nucleic acid surrounded by a very thin layer of protein. Viruses can be purified and obtained in the form of crystals like many organic substances. Some of the human diseases such as mumps, smallpox, chicken-pox, measles, yellow fever, scarlet fever, infantile paralysis, influenza, common cold, cancer, hydrophobia, etc., are supposed to be caused by viruses. Among plants the mosaic disease of potato, tomato, tobacco, gourds, cucumbers, ground nut, etc., the yellow disease of peach, curly top of beet, radish, cabbage, turnip, etc., and necrosis (necrotic disease) of potato and tomato are said to be caused by viruses.

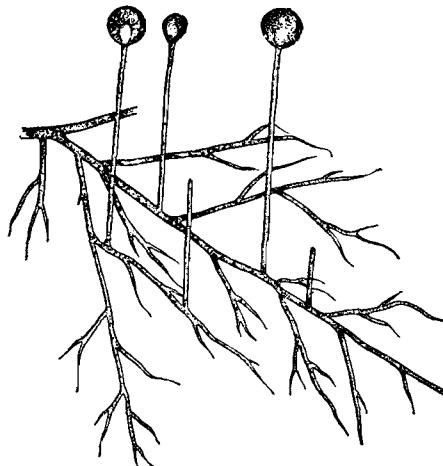

CHAPTER 4 *Fungi*

1. *MUCOR* (50 sp.)

Occurrence. *Mucor*, commonly called 'pin-mould', is a saprophytic fungus. It grows on horse-dung, wet shoes, stale moist bread, rotten fruit, shed flowers and other organic media, spreading like a cobweb. It can be easily grown in the laboratory on a piece of moist bread kept under a bell-jar in a warm place for three or four days.

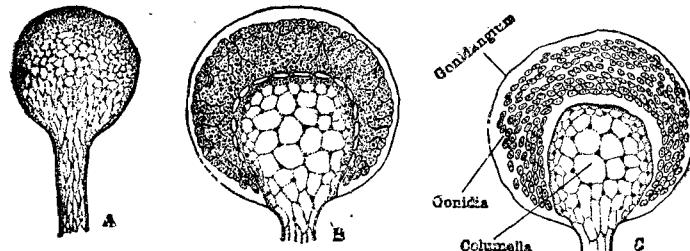

Structure. The plant body is composed of a mass of white, delicate, cottony threads collectively known as the **mycelium**

(fig. 393). It is always very much branched, but is coenocytic, i.e. unseptate and multi-nucleate. Each individual thread of the mycelium is known as the **hypha** (pl. hyphae).

Mucor. FIG. 393. Ramifying mycelia with some sporangia (or gonidangia).

conditions of moisture and temperature. It is seen that mycelia give off here and there numerous slender erect hyphae, each ending in a spherical head—the *sporangium* (fig. 394). The protoplasmic contents migrate to the spherical head (A) and become differentiated into two distinct regions—the outer and the inner. The outer region is dense and contains numerous nuclei, while the inner region is thin and vacuo-

Mucor. FIG. 394. Development of sporangium, spores and columella; A, the end of the hypha swells; B, two regions—dense and light—are apparent with a layer of vacuoles between them; and C, mature sporangium (or gonidangium) with spores (or gonidia) and dome-shaped columella.

late and contains few nuclei (B). A wall soon appears round the central region, separating it from the outer one. The central region, which is dome-shaped and sterile, i.e. without

spores, is called **columella** (C). The protoplasm of the outer region breaks up into a large number of small multinucleate masses. Each mass is a **spore**. Its wall thickens and darkens. The wall of the sporangium is thin and brittle. Finally as the columella swells owing to accumulation of a fluid in it, it exerts a pressure on the wall of the sporangium which as a consequence bursts, setting the spores free. The spores are blown about by the wind. Sooner or later under favourable conditions they germinate in a suitable medium and grow directly into the *Mucor* plant.

Sexual Reproduction. Sexual reproduction takes place by the method of **conjugation** (fig. 395) only under certain conditions, particularly when the food supply becomes exhausted. Conjugation consists in the fusion of *two similar gametes*, i.e. isogametes (cf. *Spirogyra*). The process is as follows. When two hyphae borne by *two different plants of opposite sexes* (called the + strain and the - strain) come close together, two short swollen protuberances, called the conjugation tubes, develop, forming a contact at their tips (A). As they elongate they push

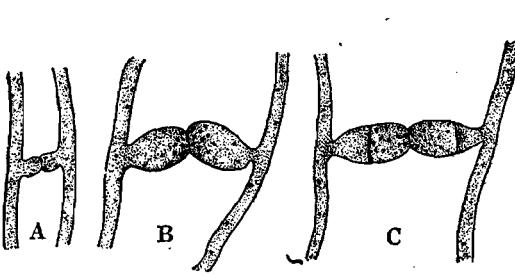

FIG. 395

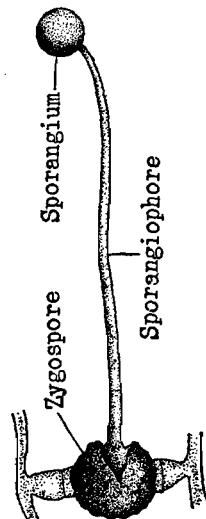

FIG. 396

Mucor. FIG. 395. Conjugation : A-E are stages in the process; note the thick-walled zygospore at E. FIG. 392. Germination of zygospore.

the parent hyphae apart from each other. Each tube enlarges and becomes club-shaped (B). Soon it is divided by a partition wall into a basal **suspensor** and a terminal **gametangium** (C).

The protoplasmic contents of each gametangium constitute the gamete. The gametes, like the spores, are multinucleate. The two gametes are identical in all respects. The end- (or common-) walls of the two gametangia get dissolved, and the two gametes fuse together (D) and form a **zygospore** (E). The zygospore swells into a rounded body, and its wall thickens, turns black in colour and becomes warted. It contains an abundance of food, particularly fat globules.

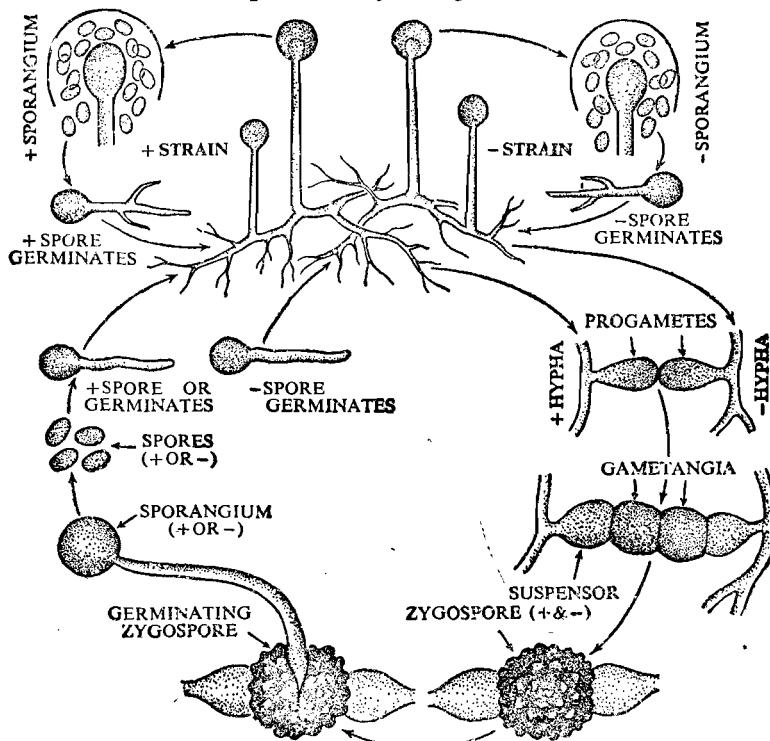

FIG. 397. Life-cycle of *Mucor*.

Sometimes it so happens that conjugation does not take place, and then a gametangium may be converted into a zygospore-like body called the **azygospore**. Germination of the azygospore has not been followed.

Germination of Zygospore (fig. 396). The zygospore undergoes a period of rest and then it germinates. The outer wall bursts and the inner wall grows out into a tube, called the **sporangio-phore** or **promycelium**, which ends in a spherical sporangium.

The sporangium contains numerous small **spores** but no columella. The spore germinates, giving rise to the *Mucor* plant.

COMPARATIVE STUDY OF *SPIROGYRA* AND *MUCOR*

Habit and Habitat. *Spirogyra* is a green alga floating in stagnant water; while *Mucor* is a saprophytic fungus growing in horse-dung, stale bread, wet shoes, rotting fruit and vegetables, etc. *Spirogyra* manufactures its own food; while *Mucor* absorbs ready-made food from the substratum. Carbohydrate is in the nature of starch in *Spirogyra*; while it is glycogen in *Mucor*.

Structure. Each *Spirogyra* plant is a slender unbranched filament consisting of a row of cylindrical cells; while *Mucor* consists of a mycelium which is a network of white much-branched cottony threads (hyphae). Each cell of *Spirogyra* filament contains one or more spiral bands of chloroplasts with numerous pyrenoids in them, and one nucleus. In *Mucor* on the other hand each hypha is coenocytic, i.e. unseptate and multinucleate.

Reproduction. There is no regular vegetative reproduction in *Spirogyra* or *Mucor*. The normal method of reproduction is sexual in *Spirogyra* (asexual method being absent), and asexual in *Mucor* (sexual method being conditional).

(a) **Asexual Reproduction.** This is absent in *Spirogyra*, whereas in *Mucor* this is the commonest mode of reproduction. Thus the latter reproduces asexually by innumerable minute spores borne in sporangia, each at the end of an erect hypha. Each spore germinates and grows into a *Mucor* plant.

(b) **Sexual Reproduction.** In *Spirogyra* sexual reproduction is commonly in the nature of scalariform conjugation; while in *Mucor* conjugation takes place between two hyphae (conjugating hyphae) of opposite sexes only under certain conditions. In *Spirogyra* the zygote directly germinates into a new filament; while in *Mucor* it grows into a sporangiophore which ends in a sporangium with spores. The spores then germinate into *Mucor* mycelia.

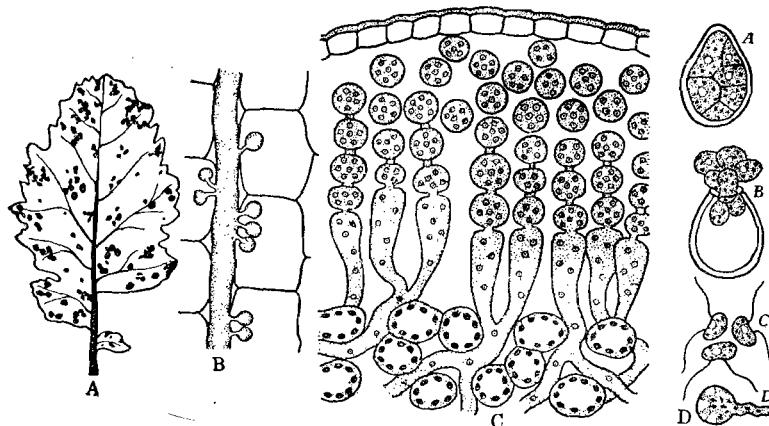

(c) **Parthenogenesis.** In both *Spirogyra* and *Mucor*, if conjugation fails, a gametangium may be converted into a thick-walled spore called azygospore.

2. *ALBUGO* (25 sp.)

Occurrence. *Albugo* (*Cystopus*) *candida* (fig. 398) is a common 'downy mildew'. It grows as a parasite on many plants of the mustard family, e.g. mustard, radish, cabbage, turnip, etc., and causes a disease called 'white rust'. White blisters appear on the stem and the leaf (A). Gradually the disease spreads to the flowers and the ovaries. The disease is not a serious one in India.

Structure. The mycelia ramify through the intercellular spaces of the host plant and branch profusely. The hyphae are unseptate and multinucleate. Here and there they send globular or button-like haustoria (B) into the living cells of the host to absorb food from them.

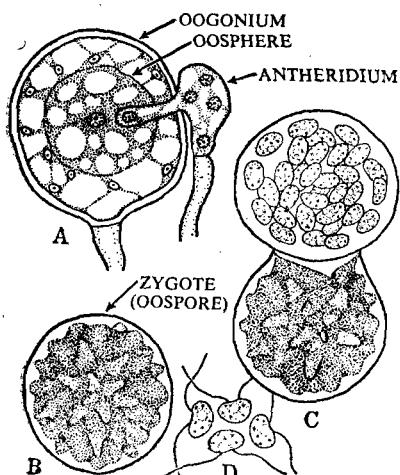

Reproduction. The fungus reproduces both asexually and sexually.

Albugo. FIG. 398. A, an infected leaf of mustard; B, an intercellular hypha with button-like haustoria; C, an infected leaf in section showing chains of multinucleate sporangia under the epidermis (note the necks separating the sporangia); D, germination of a sporangium; A, sporangium dividing; B, zoospores escaping; C, biciliate zoospores swimming; and D, a zoospore germinating.

Asexual Reproduction (fig. 398 C-D). Hyphae grow luxuriantly at certain points below the epidermis of the host, and form clusters of erect club-shaped multinucleate hyphae (sporangiophores) which begin to cut off multinucleate **sporangia** in chains at the tips. The sporangia are separated from

one another by short necks made of gelatin. The epidermis soon gets ruptured and the sporangia appear on the surface as a white powdery mass. The sporangia are now blown by the wind to other plants. The contents of each sporangium (D, A) divide to form a few (4 or 8 or more) **zoospores**, each with two lateral cilia. The sporangium bursts and the zoospores escape (D, B). They swim in water for some time (D, C). Soon they lose their cilia, cover themselves with a wall and come to rest. Later they germinate by producing a **germ-tube** (D, D) which enters the host plant through a stoma. Sometimes a sporangium germinates directly without forming zoospores.

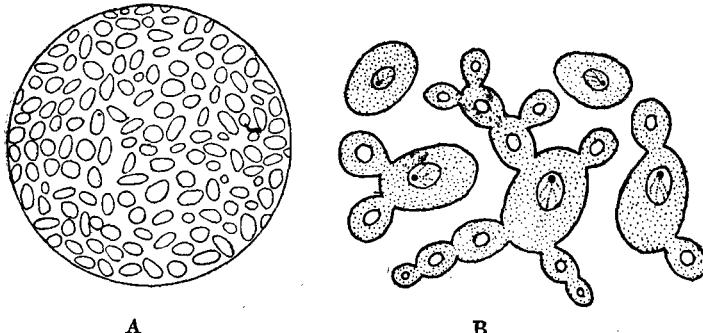

Albugo. FIG. 399. A, fertilization; B, zygote (oospore); C, germination of zygote; zoospores escaping into a vesicle; and D, biciliate zoospores after escape.

Sexual Reproduction (fig. 399). In the intercellular spaces of the host the hyphae form separately male and female organs called **gametangia**. The tip of a hypha swells and gives rise to a spherical multinucleate female gametangium called the **oogonium**. It shows two distinct zones: a dense central zone called the **ooplasm**, which is the **egg-cell** or oosphere with an **egg-nucleus** in it (other nuclei of this zone usually degenerate), and a lighter multinucleate outer zone called the **periplasm**. Similarly the tip of another hypha close to the oogonium swells and gives rise to a club-shaped multinucleate male gametangium called the **antheridium**. It soon comes in contact with the wall of the oogonium and produces a beak or **fertilization tube** which penetrates into the oosphere. One or more male nuclei are set free through this tube but only one of them fuses with the egg-nucleus. Thus fertilization is effected (A). The zygote (oospore) formed as a result of fertilization covers itself with a thick wall (B). The periplasm is used up in the process. The zygote is liberated only after the decay of the host tissue. Later it produces numerous (over 100) small zoospores which escape into a vesicle (zoosporangium; C). Each zoospore develops two cilia laterally. The vesicle dissolves and the zoospores are set free to swim about in water (D). Finally they germinate under appropriate conditions by producing a **germ-tube** which infects the host.

3. SACCHAROMYCES (40 sp.)

Occurrence. Yeast (*Saccharomyces*) grows abundantly in sugar solution such as the juice of date-palm, grapes, etc.; it has the property of changing sugar into alcohol. This special power of yeast has been taken advantage of in the manufacture of toddy, alcohol, wine, beer, etc. Yeast is also used in the

Yeast. FIG. 400 A-B. A, yeast cells as seen under the microscope; B, budding.

making of bread, its sponginess being due to the production of CO_2 during fermentation. It is also used as a medicine because of its high vitamin content.

Structure (fig. 400). Its structure is simple. A single cell represents the whole body of the plant. It is very minute in size

and looks like a pinhead under the microscope (A). Each cell is oval or almost spherical, provided with a distinct cell-wall, and contains a mass of cytoplasm with one or more vacuoles and a single nucleus. The nucleus contains a large vacuole, and this nuclear vacuole is a peculiarity of yeast. In the vacuole lies the nuclear reticulum (C). Embedded in the cytoplasm there are granules of glycogen, several oil-globules, and also protein compounds.

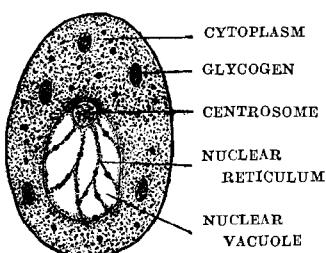

FIG. 400C. One yeast cell (magnified) showing the nuclear vacuole.

glutathione, and also protein compounds.

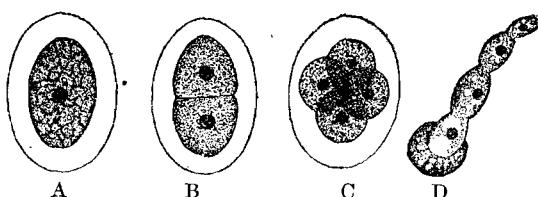

In the vacuole lies the nuclear reticulum (C). Embedded in the cytoplasm there are granules of glycogen, several oil-globules, and also protein compounds.

Reproduction may be vegetative, asexual and sexual (in some species).

Vegetative Reproduction (fig. 400 B). This is a common method in yeast cells growing in sugar solution. As they grow, two changes are noticed: budding of yeast cells, and alcoholic fermentation of sugar solution (see p. 299). **Budding**. In this process each cell gives rise to one or more tiny outgrowths which gradually increase in size and are ultimately cut off from the mother cell; these then lead a separate existence. The budding may be repeated, resulting in the formation of one or more chains and even sub-chains of bead-like cells; these cells ultimately separate from one another into individual one-celled yeast plants.

Asexual Reproduction (fig. 401). When the food supply is scanty or exhausted but oxygen abundant the yeast cell becomes larger and behaves as a sporangium, called the **ascus** (A).

Yeast. FIG. 401.
A, an ascus;
B-C, formation of
ascospores;
D, ascospore
germinating.

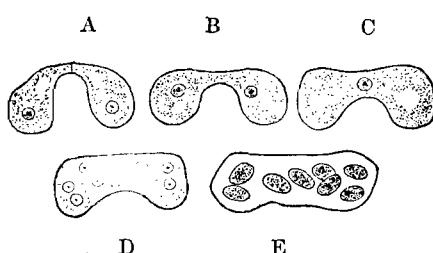

The nucleus of the ascus divides twice to form four spores, called **ascospores** (B-C), each provided with a firm wall. Instead of four spores, sometimes two or eight may be formed. These are the resting spores, and can withstand unfavourable conditions of life. The wall of the ascus ruptures, and the

ascospores are blown about by the wind. When they get a suitable medium they germinate and reproduce by the process of budding (D).

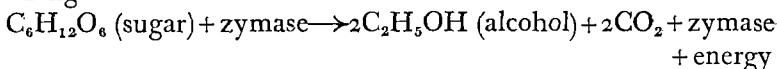

Sexual Reproduction (fig. 402). Some species of yeast also reproduce sexually by conjugation. In this process two adjacent cells send out short protuberances which unite with each other. The two nuclei then pass on to the conjugating

Yeast. FIG. 402. Conjugation of yeast cells and formation of ascospores.

tube and fuse with each other. The zygote (**ascus**) thus formed divides to produce eight nuclei. Each nucleus clothes itself with a wall, enlarges and becomes known as the **ascospore**. The ascospore commonly germinates by budding.

Alcoholic Fermentation. When the yeast cells grow in sugar solution, as in date-palm juice, palmyra-palm juice or grape juice, they set up fermentation (see p. 247) in it by means of an enzyme (zymase). Sugar is decomposed, and alcohol and carbon dioxide are the chief products formed. Carbon dioxide escapes, and often gives rise to frothing on the surface of the solution. Fermentation takes place only when the supply of oxygen is cut off. Sugar undergoes the following chemical change:

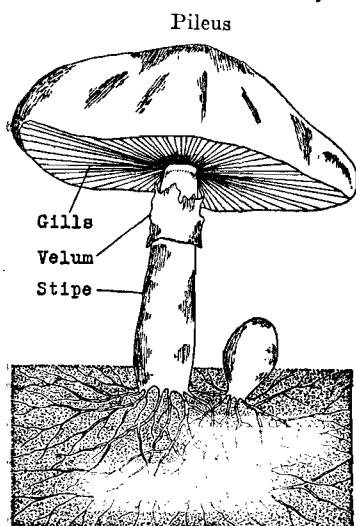

Yeast cells are very rich in digestible compounds, specially proteins, fats, carbohydrates, etc. and also enzymes and vitamins, and as such their value as food is considerable. They are purified, dried at about 125°C., and sold in the market as *Yeastvite* or under some other trade name.

4. *AGARICUS* (about 70 sp.)

Occurrence. *Agaricus*, commonly called mushroom, is a fleshy saprophytic fungus. It grows during the rainy season on damp rotten logs of wood, trunks of trees, decaying organic matter, and in damp soil rich in organic substances.

Edible and Poisonous Forms. There are about 200 species of fleshy fungi that are edible; many more are non-edible, and about 12 species distinctly poisonous. All puff-balls and many species of *Agaricus* are edible, particularly when they are young. Certain species of *Amanita* which resemble edible *Agaricus* are extremely poisonous; however, they are, usually distinguished from the latter by their possession of a cup-like structure at the base, which is wanting in *Agaricus*.

Structure (fig. 403). The mycelium consists of a much-branched mass of hyphae which unite at their points of contact and form a network in the substratum. The hyphae are septate and hyaline. The aerial portion of the fungus constitutes its main body and is the '**fructification**' or fruit-

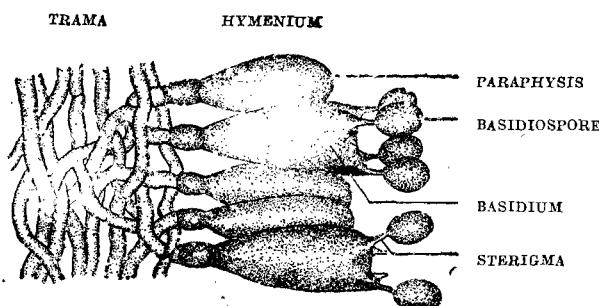

Agaricus. FIG. 403. Two plants, young and old, with ramifying mycelia.

rella-like fashion on the top of the stipe. From the under-surface of the pileus suspend a very large number of thin vertical plate-like structures, extending from the stipe to the margin of the pileus; these are known as the **gills** or **lamellae**. They vary in number from 300 to 600 for each fructification. Each gill bears innumerable spores on both surfaces.

Reproduction (fig. 404). This takes place by the asexual method only. The spores are known in this case as the **basidiospores**, and are borne by the gills on both surfaces. A gill in section shows a central portion called **trama** which is an inter-

body of the plant. It consists of a fleshy stalk known as the **stipe** and an umbrella-like head borne on its top, known as the **pileus** (a hat). The whole body of the fungus is composed of an interwoven mass of hyphae, looking in section like a tissue—a false tissue, known as pseudo-parenchyma. When young, the fructification is spherical or oval in shape (button stage) and is completely enveloped by a thin membranous covering, called the **velum**. With the growth of the pileus, the velum gets ruptured from the stipe leaving a ring (annulus). Ultimately the pileus spreads in an um-

woven mass (false tissue) of long slender hyphae. The hyphal cells of the trama curve outwards on either side of the gill and terminate in a layer of club-shaped cells, called hymenium.

Agaricus. FIG. 404. A portion of the gill in section.

Some of these cells bear spores and are called **basidia**; while others are sterile and are called **paraphyses**. Each basidium bears four **basidiospores**—in some cases two only—on short slender stalks, known as **sterigmata** (sing. *sterigma*). The basidiospores, when mature, shoot off from the sterigma and germinate under favourable conditions.

Plant Diseases caused by Fungi. *Symptoms and Causes.* Many parasitic fungi attack several field crops, cultivated and ornamental plants and even wild ones, and cause various and often serious diseases in them. The fungi plunder the food stored in the host plants, block the conducting tissues, destroy the affected cells and tissues, produce toxins (poisons) and finally cause their death. The annual loss in agricultural crops on this account alone is very heavy. A plant may suffer from more than one disease at a time. Some of the common fungal diseases are as follows. (1) **Leaf Spot Disease** is a common disease appearing on the leaves of a variety of plants as brown, orange-red or black patches or spots, caused by a number of parasitic fungi. The disease may spread from one part to another and destroy the affected plants, e.g. *late blight* of potato (caused by *Phytophthora*), *leaf-spot* of rice (caused by *Helminthosporium*)—the fungus also attacks and destroys the grains, '*tikka*' disease of groundnut (caused by *Cercospora*), etc. (2) **Rust Disease** is a serious disease of wheat and other cereals (caused by *Puccinia*). The disease appears in the form of reddish, orange or black spots and streaks on the leaf, leaf-sheath and stem. (3) **Smut Disease** is another serious disease of wheat, barley, maize, oats and sugarcane (caused by *Ustilago*). The disease is very widespread. The fungus mainly attacks the flowers and often the whole inflorescence. The infected parts turn black and all the grains are often totally destroyed. (4) **Mildews** appear on the leaves as whitish, yellowish or brownish spots and are caused by a number of fungi, e.g. *downy mildews* of mustard, radish, cauliflower, cabbage, etc. (caused by *Albugo* and others) and *powdery mildews* of rose, pea, bean, barley, apple and *Phlox* (caused by

Erysiphe and others). (5) **Red Rot** of sugarcane (caused by *Colletotrichum*) is a very serious and destructive disease in India. Many other fungal diseases affecting various plants are also common. For **bacterial diseases**, see pp. 289-90.

Control. *Prevention, Check and Cure.* Considering the heavy economic loss due to diseases the following methods have been devised to prevent them, to destroy the causative fungi and to keep them under check. (1) Spraying or dusting of the affected parts with certain poisonous chemicals called fungicides, e.g. copper sulphate, sulphur, sulphur-lime, quicklime, etc., or a mixture of them. (2) Fumigation (exposure to fumes) with sulphur dioxide gas. (3) Seed treatment—cautious application of hot water, formaldehyde or certain compounds of copper, sulphur or mercury. (4) Soil sterilization by burning wood or straw in the field or by application of steam or some poisonous chemicals. (5) Selection of disease-free seeds and plants. (6) Eradication and destruction of diseased plants. (7) Destruction of disease-carrying insects. (8) Breeding of disease-resistant varieties of plants. (9) Rotation of crops—growing some other crop in place of the existing one for one or more years.

Antibiotics. Antibiotics (*anti*, against; *bios*, life) are toxic chemical substances, possibly enzymes, secreted by certain soil bacteria and soil fungi, which have a destructive effect on particular disease germs invading the human body and causing infectious diseases, often of a serious nature, e.g. pneumonia, typhoid, diphtheria, tuberculosis, cholera, erysipelas, etc. Antibiotics are the miracle drugs of modern times. They often act like magic bullets shooting down the germs which have invaded the human body. Within the last 15 years or so some 300 antibiotics have been discovered. Of these about 13 have an established therapeutic value. The first antibiotic was a 'chance' discovery. It is **penicillin** discovered by the late Sir Alexander Fleming, a bacteriologist, in 1928 from a blue-green mould of the soil, called *Penicillium notatum*. It has a powerful antibacterial action and is amazingly effective against a wide range of germ diseases like scarlet fever, rheumatic fever, sore throat, wound infections, erysipelas, abscesses, carbuncles, tonsilitis, tetanus, pneumonia, meningitis, etc. It came into general use from 1943-44 when mass production was well under way. Other antibiotics isolated from certain soil bacteria, particularly species of *Streptomyces*, came in fairly quick succession. Thus **streptomycin** was discovered by Waksman in 1944; it has proved to be very valuable against tuberculosis. Vigorous search for more antibiotics went on at this time at an almost incredible cost, and several thousands of soil samples were examined in this connexion. Soon another antibiotic called **chloromycetin** was discovered in 1947; it has proved to be a magic drug in the treatment of typhoid fever. Within the following few years some more antibiotics, **aureomycin**, **terramycin**, etc., have been discovered and put on the market for the treatment of one kind of bacterial disease or another. These wonder drugs have saved millions of human lives from death or from untold miseries, and that too within the shortest time possible. It is really a miracle that such drugs lay hidden in a spoonful of good earth for the relief of human sufferings.

CHAPTER 5 *Bryophyta*

1. *RICCIA* (135 sp.)

Riccia (fig. 405) is a rosette type of thalloid liverwort showing distinct dichotomous branching. The thallus is small and flat with a longitudinal groove on the upper surface along the midrib, and a number of slender unicellular hair-like structures, called **rhizoids**, on the lower surface, serving as roots. Some scales may also be present. The plant grows during the rainy season as a green carpet on wet ground, old damp walls, old tree trunks and moist rocks, and dries up in winter.

Vegetative Reproduction may take place by the decay of the older portion of the thallus and the separation of the branches.

Gametophyte and Sexual Reproduction. The *Riccia* plant is a **gametophyte**, i.e. it reproduces sexually by gametes. The two kinds of gametes—male and female—are borne in special structures known as the antheridia and the archegonia respectively (fig. 406). Some species are *monoecious* and others *dioecious*. In the monoecious species antheridia and archegonia develop together in the median groove on the upper side of the thallus. Each **antheridium** (A) is more or less pear-shaped and consists of a short stalk, a wall and a compact mass of antherozoid mother cells. Each mother cell by a single division forms two cells, each of which becomes converted into a small twisted biciliate male gamete or **antherozoid** (B). Each **archegonium** (C-D) also lies sunken in the groove. It is a short-stalked, flask-shaped body with a swollen basal portion known as the **venter** and a narrow tubular upper portion known as the **neck** which often projects beyond the epidermis and turns purplish. The neck contains a few neck canal cells surrounded by a wall, and the venter is occupied by a large cell—the **egg-cell** with a distinct large nucleus in it—the **egg-nucleus** (female gamete). The canal cells degenerate into mucilage.

Fertilization. The antherozoids swim to the archegonium. The mucilage swells and forces out the cover cells of the archegonium (D). An open passage is thus formed, and the

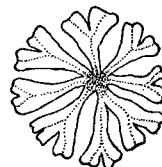

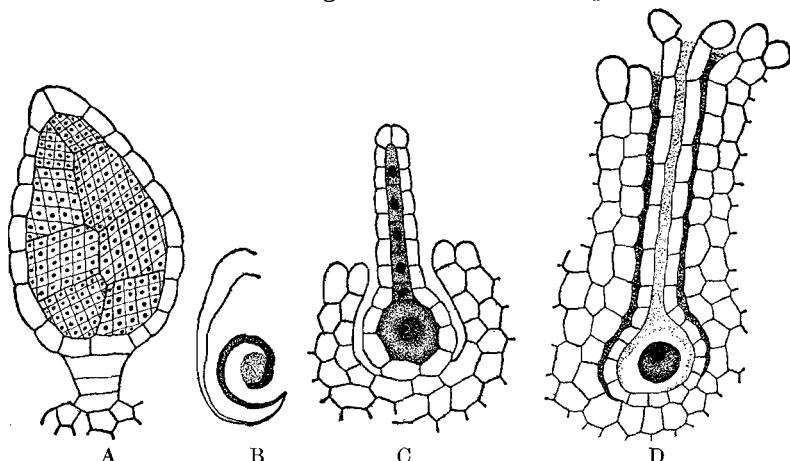

FIG. 405. A *Riccia* plant.

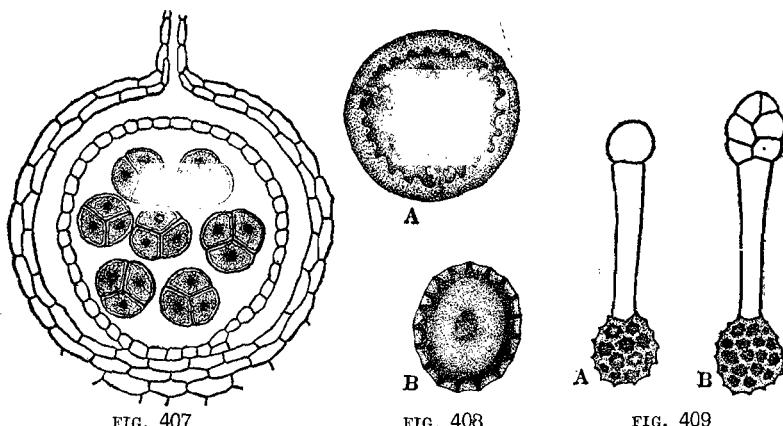

antherozoids enter through it into the archegonium. They

Riccia. FIG. 406. *A*, an antheridium; *B*, an antherozoid; *C*, a young archegonium; and *D*, a mature archegonium.

pass down into the venter and one of them fuses with the egg-nucleus. After fertilization the ovum clothes itself with a wall and becomes the **oospore**.

Sporophyte and Asexual Reproduction. The oospore gives rise to the **sporophyte** which reproduces asexually by spores.

Riccia. FIG. 407. Sporophyte (capsule) within enlarged archegonium.
FIG. 408. Spore; *A*, spores in a tetrad; *B*, a single spore. FIG. 409.
A-B, early stages in the germination of spore.

The sporophyte is a simple spherical body called the **capsule** (fig. 407). It consists of a spore-sac and a wall surrounding it,

the latter made of a single layer. The capsule develops *in situ* within the venter of the archegonium. With the growth of the capsule the venter also grows and covers the capsule; this covering is called the **calyptora**. The spore-sac contains a loose mass of spore mother cells. Each mother cell undergoes reduction division and forms a *tetrad of spores* (fig. 408A). Eventually by the rupture of the calyptora and the wall of the capsule the spores are set free. Each spore (fig. 408B) is provided with a thick coat. The spore germinates at first into a short tube called the *germ-tube* (fig. 409) which gradually develops into *Riccia* thallus.

Alternation of Generations. The plant passes through two successive generations—gametophyte and sporophyte—to complete its life-history. The gametophyte begins with the spore and ends in the formation of the gametes; while the sporophyte begins with the oospore and ends in the spore mother cells. The gametophyte gives rise to the sporophyte through sexual reproduction, and the sporophyte to the gametophyte through asexual reproduction. Thus there is a regular alternation of generations in *Riccia*.

2. MARCHANTIA (65 sp.)

Marchantia (figs. 410-11) is a rosette type of thalloid liverwort (much larger than *Riccia*) showing conspicuous dichotomous branching with a distinct mid-rib. It grows on damp ground and old walls and spreads rapidly during the rainy

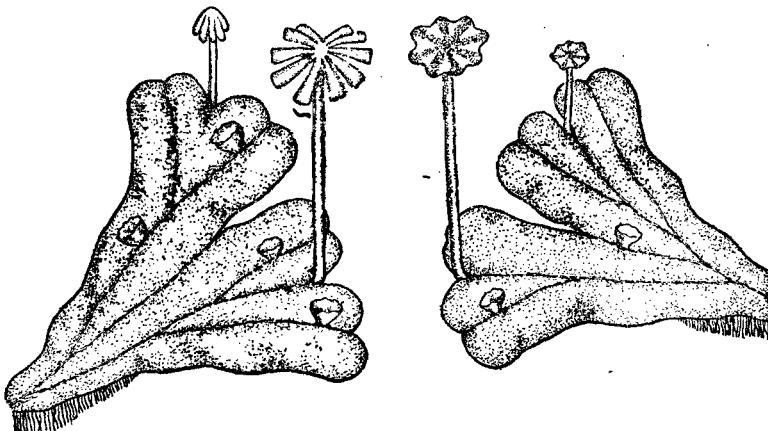

FIG. 410

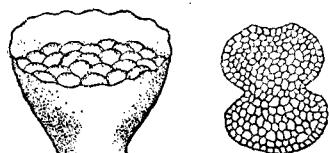

FIG. 411

Marchantia. FIG. 410. Female plant with archegoniophores and gemma-cups.
FIG. 411. Male plant with antheridiophores and gemma-cups.

season, forming a sort of green carpet. It grows luxuriantly in the cold climate of the hills. The plant dries up in winter.

The thallus bears on its undersurface a number of unicellular **rhizoids** (hair-like structures functioning as roots), and also rows of scales. On the upper surface it bears a number of cup-like outgrowths, known as the gemma-cups, on the midrib. *Marchantia* is dioecious. The male plant bears some special erect *male* reproductive branches (antheridiophores), each with a more or less circular disc or **receptacle** on the top (fig. 411). Similarly, the female plant bears special *female* branches (archegoniophores) with a star-shaped disc or **receptacle** with radiating rays or arms (fig. 410). The growing point of the thallus lies in its groove.

Vegetative Reproduction may take place (*a*) by the decay of the old basal portion of the thallus, thus separating a branch

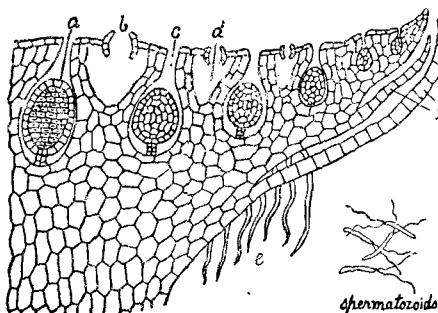

Marchantia. FIG. 412. *A*, a gemma-cup with gemmae; *B*, a gemma.

or (*b*) by **gemmae** (fig. 412B) which develop in the **gemma-cup** (fig. 412A). Each gemma is a small, more or less circular, flattened structure with a conspicuous depression on each side. When the gemmae get detached from the gemma-cup, each grows out into a dichotomously branched green thallus.

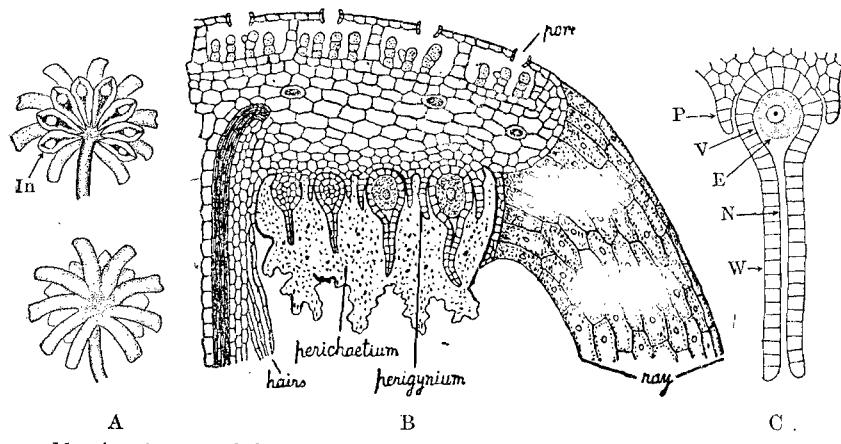

Gametophyte and Sexual Reproduction. A *Marchantia* plant is the gametophyte, i.e. it reproduces sexually by gametes. The

male plant bears antheridia (or male organs) on the upper side of the receptacle of the antheridiophore (fig. 413); and the female plant bears archegonia (or female organs) on the lower side of the receptacle of the archegoniophore (fig. 414).

The **antheridium** (fig. 413a) is an ovoid body composed of a mass of antherozoid mother cells and surrounded by a wall. Each mother cell develops a spindle-shaped biciliate male gamete called the **antherozoid** or spermatozoid. The antherozoids escape through a narrow canal known as the **ostiole** (c). Besides, the receptacle has a number of air-pores (b) and air-chambers (d). The **archegonium** (fig. 414 b-c) is a flask-shaped body consisting of a swollen basal portion, the **venter**, and a narrow tubular portion, the **neck**. The venter contains a large cell, the **egg-cell**, with a distinct large **egg-nucleus** in it. The neck contains a few neck canal cells and a wall around it. Surrounding a group of archegonia a curtain-like outgrowth known as the **involucrum** (or perichaetium), fringed at the edges, is formed as a protective covering. Also, a cup-shaped outgrowth known as the **pseudo-perianth** (or perigynium) is formed at the base of each archegonium, later surrounding it after fertilization. The receptacle further bears air-pores and air-chambers with chains of green cells in them.

Marchantia, FIG. 414. A, (top) undersurface of the archegoniophore; In., involucrum; (bottom) upper surface of the same; B, section through the archegoniophore showing archegonia, etc. (see text); C, an archegonium; P, pseudo-perianth (or perigynium); V, venter; E, egg-cell; N, neck; W, wall.

Fertilization. After the antheridium bursts, the ciliâte antherozoids escape through the ostiole and swim to the archegonium through the medium of dew or rain-water. Many of them enter into the venter through the neck. But only one of them fuses with the egg-nucleus. Fertilization is thus

effected. After fertilization the egg-cell or ovum develops a wall round itself and becomes the **oospore**.

Marchantia. FIG. 418. Sporogonium dehiscing and discharging spores; *P*, perigynium; *S*, seta; *C*, capsule; and *S'*, spores.

Sporophyte and Asexual Reproduction

(figs. 415-16). The oospore germinates *in situ* and gives rise to the sporophyte which reproduces asexually by spores. The sporophyte is a complex body and is known as the **sporogonium**. It consists of a **foot**, a short stalk called **seta**, and a **capsule**. The capsule consists of a single-layered wall, and a mass of small cells. Some of these cells grow up into elongated, spindle-shaped, spirally thickened structures called **elaters** (figs. 416-17), while others form **spore mother cells**. Each spore mother cell undergoes reduction division and forms **four spores** in a tetrad. Other parts of the archegoniophore also grow. Thus

the wall of the venter grows and forms the **calyptra** which surrounds the capsule (fig. 416c); the neck withers and disappears. The **perigynium** (figs. 415E & 416D) grows rapidly and ultimately surrounds the sporogonium. Finally the capsule dehisces rather irregularly, and the spores are discharged (fig. 418). Under humid conditions the elaters undergo a twisting movement and push the spores out of the capsule. The spore germinates and gives rise to a short tube which develops into the *Marchantia* thallus.

Alternation of Generations *Marchantia* shows two stages or generations in its life-history. The plant itself is the gametophyte and the sporogonium is the sporophyte. The gametophyte reproduces sexually by gametes and gives rise to the sporophyte, and the sporophyte reproduces asexually by spores and gives rise to the gametophyte. Thus the two generations regularly alternate with each other.

3. MOSS

Moss (fig. 419) occurs most commonly on old damp walls, trunks of trees, and on damp ground during the rainy season, while in winter it is seen to dry up. It forms a green patch

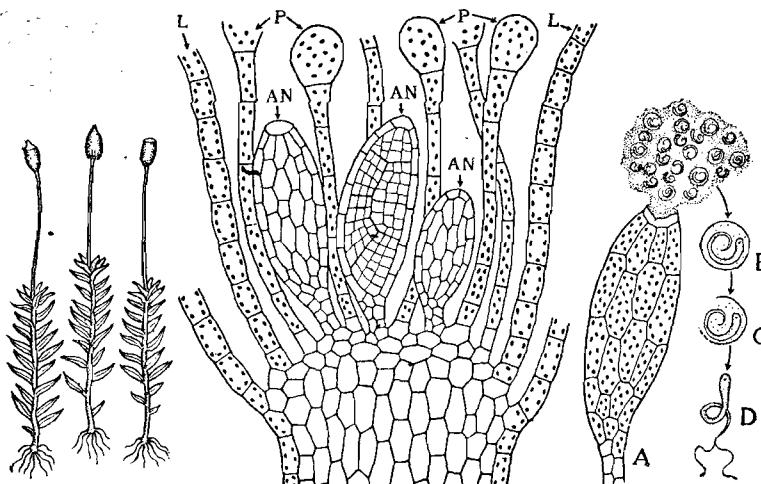

FIG. 419

FIG. 420

FIG. 421

Moss. FIG. 419. Three moss plants. FIG. 420. Apex of a moss shoot in section showing antheridia (AN), paraphyses (P) and leaves (L). FIG. 421. A, a mature antheridium discharging antherozoid mother cells; B, an antherozoid mother cell; C, wall of the mother cell dissolving; and D, a biciliate antherozoid.

or a soft velvet-like, green carpet. A moss plant is small, usually 2-3 cm. or so in height, and consists of a short axis with spirally arranged minute green leaves which are crowded towards the apex. True roots are absent but the plant bears a number of slender multicellular branching threads called **rhizoids** which perform the functions of roots. The axis may be branched or unbranched.

Gametophyte and Sexual Reproduction. The moss plant is a **gametophyte**, i.e. it bears gametes and reproduces by the sexual method. For the purpose highly differentiated male and female organs are developed, either together at the apex of the same shoot, or separately on two, often intermixed with some multicellular hair-like structures called **paraphyses**. The male organ is known as the **antheridium** (figs. 420-21) and the female organ as the **archegonium** (figs. 422-23). The **antheridium** (figs. 420-21) is a multicellular, short-stalked,

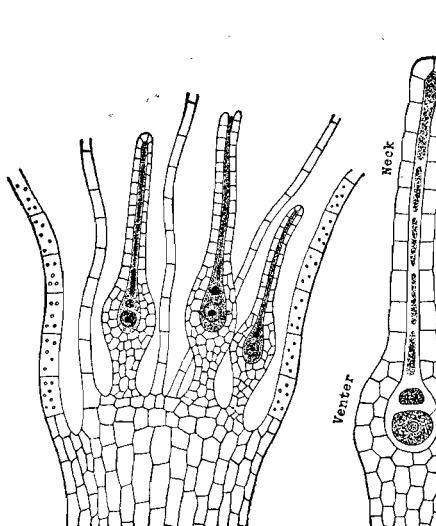

FIG. 422

Moss. FIG. 422. Apex of a moss shoot in section showing three archegonia, three paraphyses and two leaves. FIG. 423. An archegonium. FIG. 424. A moss plant showing the sporophyte growing on the gametophyte.

club-shaped body filled with numerous small cells, known as the antherozoid mother cells. The antheridium bursts at the apex and the mother cells are liberated through it in a mass of mucilage (fig. 421). The mucilaginous walls of the mother

cells get dissolved in water and the antherozoids or male gametes are set free. They are very minute in size, spirally coiled and biciliate; after liberation they swim in water that collects at the apex of the moss plant after rain. The **archegonium** (figs 422-3) is a multicellular, flask-shaped body. It consists of a short multicellular stalk, a lower swollen portion—the **venter** (belly), and an upper tube-like portion—the **neck**. The venter contains a large cell—the **egg-cell** with a distinct **egg-nucleus** (female gamete) in it. The neck is long and straight and contains many small neck canal cells which soon degenerate into mucilage.

Fertilization is effected through the medium of rain-water or dew that collects on the moss plants. When the archegonium matures it secretes mucilage with cane-sugar. This attracts a swarm of antherozoids which enter through the neck canal and pass down into the venter; one of them fuses with the egg-nucleus and the rest die. After fertilization the zygote clothes itself with a wall and is then known as the **oospore**.

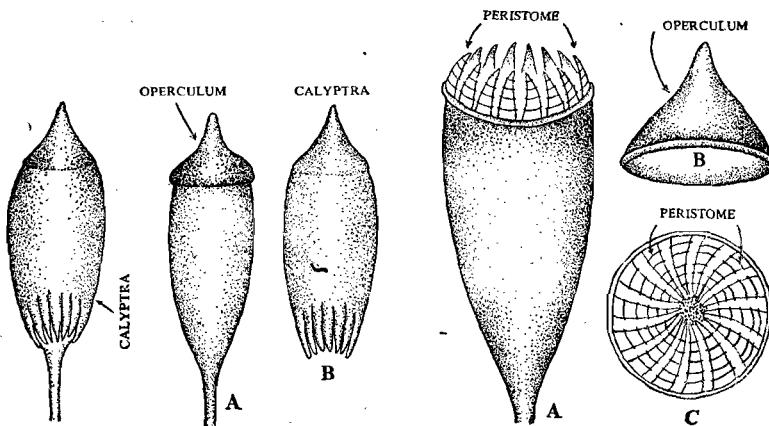

FIG. 425

FIG. 426

FIG. 427

Moss Capsule. FIG. 425. A capsule covered by calyptra. FIG. 426. A, a capsule without calyptra; B, detached calyptra. FIG. 427. A, a capsule showing peristome—open; B, operculum; C, peristome—closed (top view).

Sporophyte and Asexual Reproduction. The oospore grows *in situ* and gives rise to the sporophyte on the moss plant (fig. 424). The sporophyte reproduces asexually by spores. It is a very complex structure and is known as the **sporogonium**. It consists of **foot**, **seta** (slender stalk) and **capsule** (case con-

taining spores). The sporogonium grows as a semi-parasite on the moss plant. Although it draws most of its food from the moss plant it can manufacture its own food to some extent.

The **capsule** is a complex body with differentiated parts (fig. 428). It is covered by a sort of loose cap known as the calyptra (figs. 425-6) which is soon blown away by the wind. A longitudinal section through the capsule shows the follow-

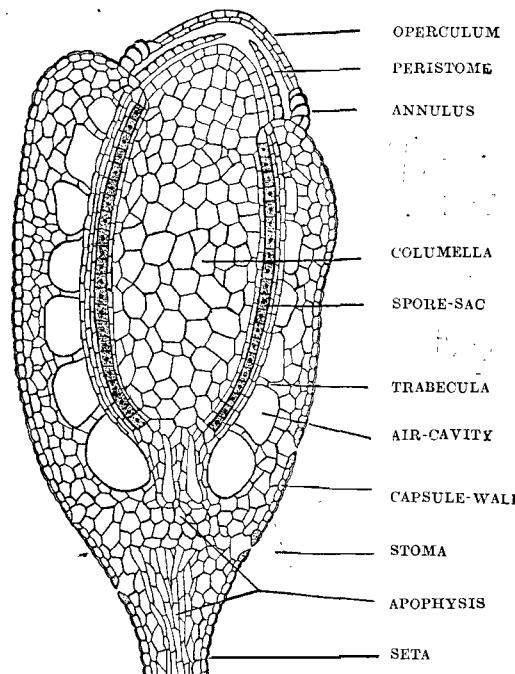

FIG. 428
Moss capsule
in longitudinal
section

ing parts. (1) **Operculum** is the circular cup-shaped lid on the top. (2) **Annulus** is the ring-like layer of thickened cells at the base of the operculum. (3) **Peristome** is one or two rings of tooth-like projections at the rim of the capsule (see fig. 427A). (4) **Columella** is the solid central column. (5) **Spore-sac** is the hollow cylindrical sac surrounding the columella and bearing numerous spores. (6) **Air-cavity** with strands of cells (trabeculae) across it. (7) **Capsule wall** with epidermis as external layer. (8) **Apophysis** is the solid basal portion of the capsule, having chloroplasts in many cells and stomata in the epidermis.

Germination of the Spore. After dehiscence of the capsule the spores are scattered by the wind, and they germinate

under favourable conditions. The spore grows into a green, much-branched filament known as the **protonema** (fig. 429). It produces here and there some slender rhizoids, and a number of small lateral buds which grow up into new moss plants. Thus the life-cycle of moss is completed.

Alternation of Generations. (fig. 430). The moss plant shows in its life-history two generations which regularly alternate with each other. The moss plant itself is the gametophyte and it reproduces sexually by gametes

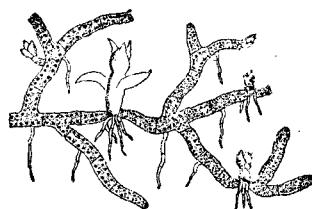

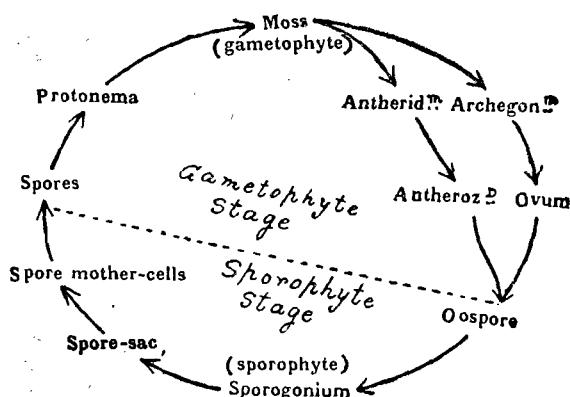

FIG. 429. Protonema of moss (note the buds and rhizoids).

(antherozoid and ovum) to give rise to the sporophyte; while the sporogonium is the sporophyte and it reproduces asexually by spores to give rise to the gametophyte. Thus the two generations regularly alternate with each other.

CHAPTER 6 *Pteridophyta*

FERNS

Ferns (fig. 431) are a big group of highly advanced cryptogams and are widely distributed all over the earth. They grow abundantly in cool, shady, moist places, both in the hills and in the plains. The stem is mostly a rhizome, but sometimes it is erect and aerial, as in **tree ferns**. Roots are adventitious (fibrous) growing profusely from the rhizome. Leaves are usually pinnately compound and circinate (rolled from the apex downwards) when young (fig. 431), the leaflets being known as the pinnae (sing. pinna). The stem and the petiole are covered with numerous brownish scales known as the **ramenta**.

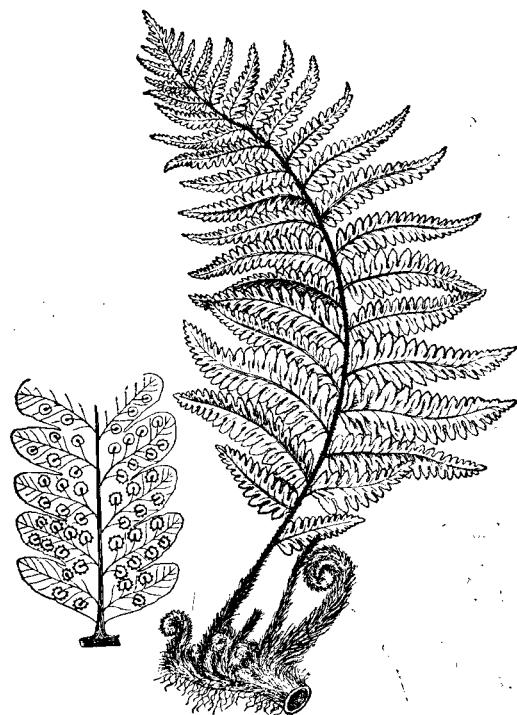

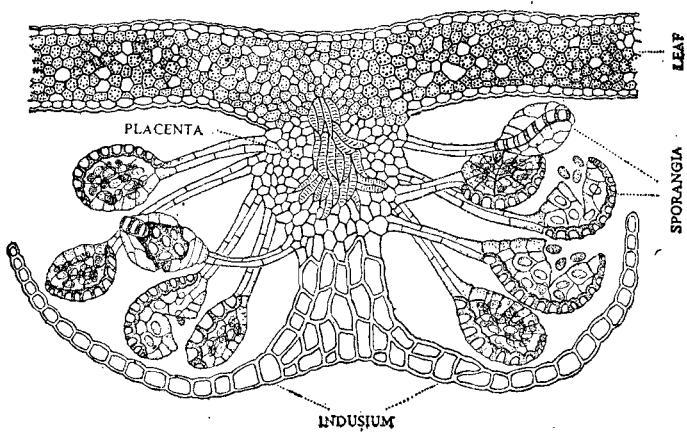

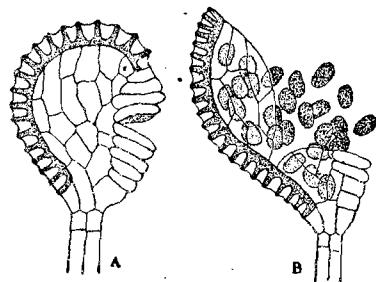

FIG. 431. A fern plant; *left*, portion of a pinna with sori.

Sporophyte and Asexual Reproduction. The fern plant (fig. 431) is the sporophyte, i.e. it bears spores and reproduces by the asexual method. On the undersurface of the leaf or the **sporophyll** (as the spore-bearing leaf is called) a number of dark brown structures, pale green when young, may be seen; these are called **sori** (sing. sorus). They develop on the veins, and are usually arranged in two rows in each leaflet or pinna of the leaf. Each sorus (fig. 432) is a group of **sporangia** (sing. sporangium) covered over by a kidney-shaped shield called the **indusium**. The sporangia and the indusium develop from a papilla-like outgrowth called the **placenta**. Each sporangium (fig. 433) consists of a long slender multicellular **stalk** and a biconvex **capsule**. The capsule is filled

Fern. FIG. 433.
Sporangium
(capsule and stalk);
A, capsule just open

with a mass of **spores**. The capsule wall is thin but it has a specially thickened and cutinized band or ring running round its margin. This ring is called the **annulus**. The annulus has an unthickened portion known as the **stomium**. When the spores mature the capsule bursts at the stomium. The annulus bends back exposing the spores, and then suddenly it returns to its original position, ejecting the spores with a jerk (fig. 433). The spore germinates and gives rise to the gametophyte.

Gametophyte and Sexual Reproduction. The gametophyte in fern is a very small (more or less 8 mm. across) green flat heart-shaped body known as the **prothallus** (fig. 434). It bears gametes and reproduces sexually by them. For this purpose the prothallus bears on its undersurface groups of highly differentiated reproductive organs called **antheridia** (male) and **archegonia** (female); it also bears many slender unicellular hair-like structures called **rhizoids** which function as roots. The **antheridium** (fig. 435) is a spherical or oval body with

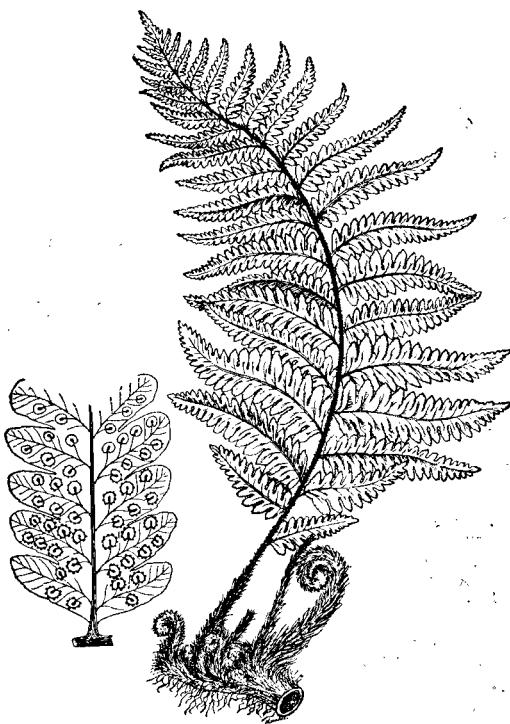

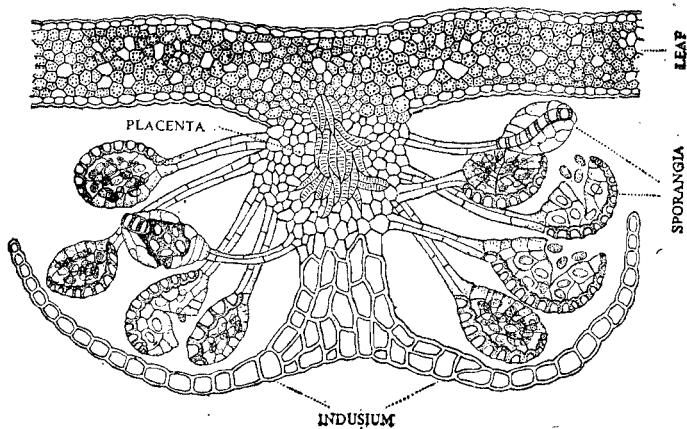

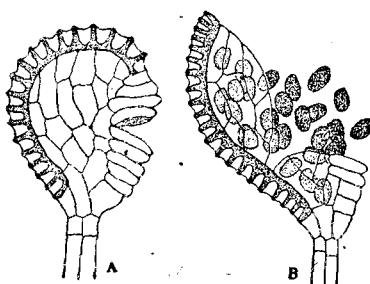

FIG. 431. A fern plant; *left*, portion of a pinna with sori.

Fern. FIG. 432. A sorus in section.

Sporophyte and Asexual Reproduction. The fern plant (fig. 431) is the sporophyte, i.e. it bears spores and reproduces by the asexual method. On the undersurface of the leaf or the **sporophyll** (as the spore-bearing leaf is called) a number of dark brown structures, pale green when young, may be seen ; these are called **sori** (sing. sorus). They develop on the veins, and are usually arranged in two rows in each leaflet or pinna of the leaf. Each sorus (fig. 432) is a group of **sporangia** (sing. sporangium) covered over by a kidney-shaped shield called the **indusium**. The sporangia and the indusium develop from a papilla-like outgrowth called the **placenta**. Each sporangium (fig. 433) consists of a long slender multicellular **stalk** and a biconvex **capsule**. The capsule is filled

Fern. FIG. 433.
Sporangium
(capsule and stalk);

with a mass of **spores**. The capsule wall is thin but it has a specially thickened and cutinized band or ring running round its margin. This ring is called the **annulus**. The annulus has an unthickened portion known as the **stomium**. When the spores mature the capsule bursts at the stomium. The annulus bends back exposing the spores, and then suddenly it returns to its original position, ejecting the spores with a jerk (fig. 433). The spore germinates and gives rise to the gametophyte.

Gametophyte and Sexual Reproduction. The gametophyte in fern is a very small (more or less 8 mm. across) green flat heart-shaped body known as the **prothallus** (fig. 434). It bears gametes and reproduces sexually by them. For this purpose the prothallus bears on its undersurface groups of highly differentiated reproductive organs called **antheridia** (male) and **archegonia** (female) ; it also bears many slender unicellular hair-like structures called **rhizoids** which function as roots. The **antheridium** (fig. 435) is a spherical or oval body with many antherozoid mother cells in it. Each mother cell pro-

duces a single twisted and multiciliate **antherozoid** (male gamete). The **archegonium** (fig. 436) is a flask-shaped body.

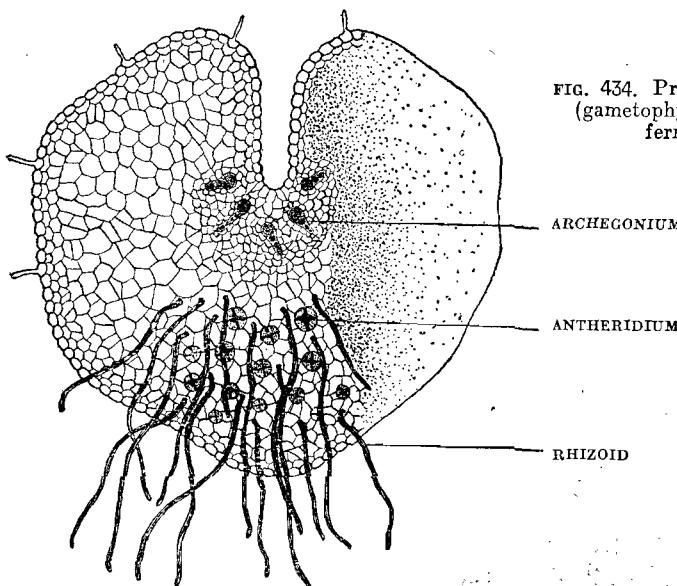

FIG. 434. Prothallus
(gametophyte) of
fern.

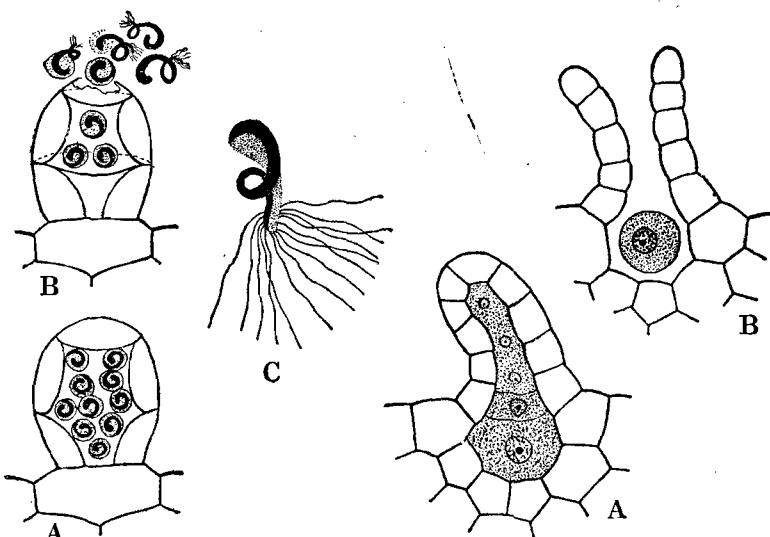

FIG. 435

FIG. 436

Fern. FIG. 435. Antheridium. A, a young one with antherozoid mother cells; B, a mature one after bursting; and C, an antherozoid. FIG. 436. Archegonium. A, a young one; and B, a mature one ready for fertilization. Note the venter and the neck.

The swollen basal portion of it is known as the **venter**, and the slender tube-like upper portion as the **neck**. The neck is short and curved in fern, and consists of a wall and a row of neck canal cells which soon degenerate into mucilage. The venter lies embedded, partly at least, in the prothallus, and encloses a single large cell — the **egg-cell** or ovum with a distinct nucleus in it — the **egg-nucleus** (female gamete).

Fertilization. After the antheridium matures and bursts the antherozoid mother cells are liberated. Their mucilaginous wall dissolves and the antherozoid of each is set free (fig. 435).

As the archegonium matures it secretes mucilage and malic acid to attract the antherozoids. They swim to the archegonium in large numbers, enter into it through the neck and pass down into the venter. They vibrate around the ovum for a while, and one of them soon fuses with the egg-nucleus. Fertilization is thus effected. The rest of the antherozoids die out. The fertilized ovum clothes itself with a cell-wall and becomes the **oospore**. The oospore gives rise to an embryo which soon develops into a young sporophyte (fig. 437). The prothallus decays and the young sporophyte grows into a fern plant.

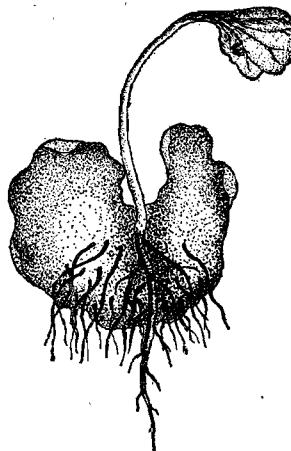

FIG. 437. Prothallus of fern with young sporophyte.

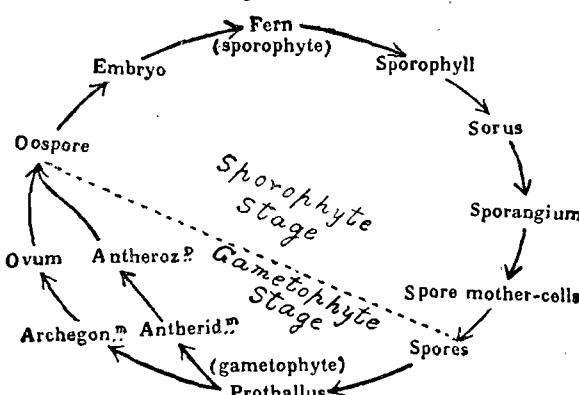

FIG. 438. Life-cycle of fern (diagrammatic) showing alternation of generations : sporophyte stage (diploid or $2n$) and gametophyte stage (haploid or n).

Alternation of Generations (fig. 438). A fern plant passes through two stages or generations to complete its life-history. The plant itself is the sporophyte, and the prothallus the gametophyte. The sporophyte or the fern plant reproduces asexually by spores and gives rise to the gametophyte or the prothallus. The prothallus reproduces sexually by gametes (antherozoid and ovum) and gives rise to the sporophyte or the fern plant. Thus the two generations regularly alternate with each other.

COMPARATIVE STUDY OF MOSS AND FERN

Habit and Habitat. Moss plants are small, usually 2-3 cm., sometimes much more in height, growing in clusters from protonemal buds forming a green soft cushion on damp ground or damp old walls; while fern plants are much bigger in size, usually 25-40 cm., growing close together in cool shady moist places.

Structure. The structure of the moss plant is simple consisting of a short axis with spirally arranged minute leaves and a number of rhizoids at the base of the axis; while the fern plant is much more complicated in structure consisting of a rhizome with scales or ramenta, several adventitious roots and usually large well-developed leaves, often pinnately divided.

Vegetative Reproduction. Moss sometimes reproduces vegetatively by splitting of protonemal branches or by resting buds on the protonema; while fern reproduces by its rhizome.

Alternation of Generations. Both moss and fern are higher cryptogams showing a regular alternation of generations in their life-history. Moss plant is the gametophyte which is the dominant phase in its life-cycle; while the sporogonium is the sporophyte which is dependent on the gametophyte as a semi-parasite. The order is reversed in the case of fern. The fern plant is the sporophyte which is the dominant phase in its life-cycle; while the prothallus is the gametophyte which although an independent body is very much reduced in size and is inconspicuous. Thus from moss to fern a reduction of gametophyte and an advance of sporophyte are evident. In both the cases the sporophyte reproduces asexually by spores and gives rise to the gametophyte and the latter reproduces sexually by gametes (antherozoid and ovum) and gives rise to the sporophyte.

PART VI GYMNOSPERMS

[**Gymnosperms** (*gymnos*, naked ; *sperma*, seed) are naked-seeded plants, i.e. those in which the seeds are not enclosed within the fruit but are directly borne by the *open carpel* (i.e. not closed to form the ovary, as in angiosperms). They form an intermediate group between the cryptogams and the angiosperms, being related to the higher forms of cryptogams on the one hand and to the lower angiosperms on the other. Gymnosperms number about 700 species. There are two main groups of them: cycads and conifers.]

CHAPTER I *Cycadaceae*

CYCAS (16 sp.)

Cycad (*Cycas*; fig. 439) is a lower gymnosperm. It consists of an unbranched erect stout and palm-like stem with a crown of fern-like pinnate leaves arranged spirally round the apex. There is a long primary (tap) root.

Cycads are dioecious, i.e. male and female flowers are borne by two separate plants. The male flower is a cone (fig. 440) borne at the apex of the stem. The male cone consists of a collection of **stamens** or microsporophylls which are arranged spirally round the axis.

Each stamen (fig. 441C) is in the form of a scale,

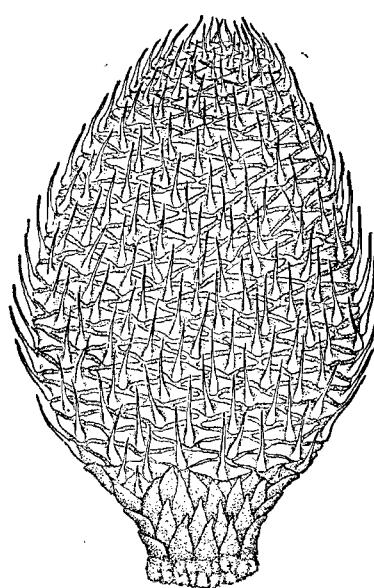

FIG. 439. A female plant of *Cycas circinalis* with carpels.

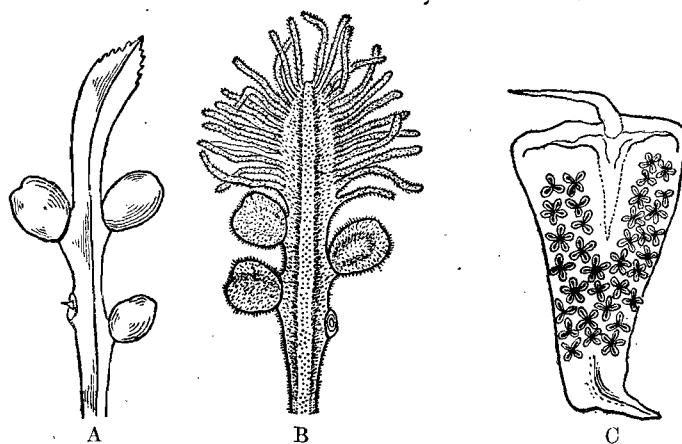

narrowed below and broadened above. It bears on its under-surface several **pollen-sacs** or microsporangia grouped in sori. There are usually 2 to 6 pollen-sacs in each sorus. In each pollen-sac there are numerous **pollen grains** or micro-spores. Each pollen grain before it is shed from the pollen-sac

produces within it an extremely reduced male pro-thallus (fig. 443) which consists of a prothallus cell, a generative cell and a tube cell.

In *Cycas* there is no proper female flower; the plant bears near its apex a rosette of **carpels** (fig. 441 A-B) which do not form a cone but are arranged alternating with the leaves. They are usually 15-30 cm. long, flattened or bent over like a hood, and often dilated above. In many species they are covered all over with soft brownish hairs. The margin of the carpel may be entire, crenate or

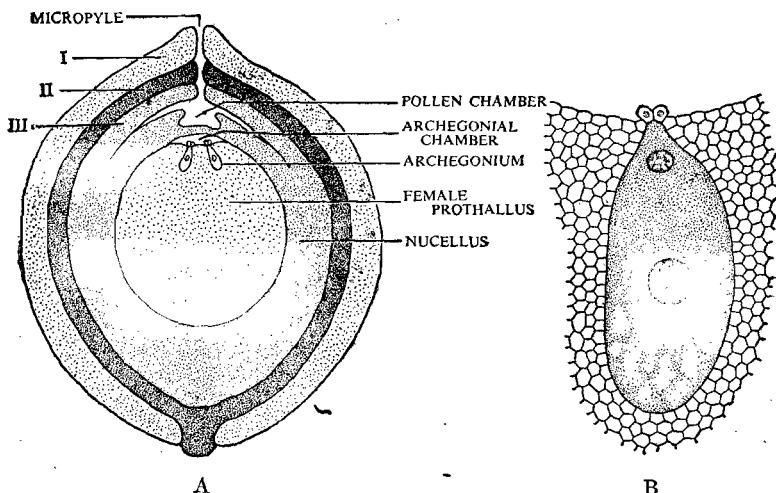

Cycas, FIG. 440. A male cone of *Cycas pectinata* with stamens.

Cycas: Carpels and Stamen. FIG. 441. A, a carpel of *Cycas circinalis*; B, a carpel of *Cycas revoluta*; C, a stamen of *Cycas pectinata* with numerous pollen-sacs.

pectinate (pinnately divided). Carpels are open, bearing usually 2-3 pairs of ovules, sometimes more, on their two margins. The ovules grow considerably even before fertilization, and are commonly oval and fairly large.

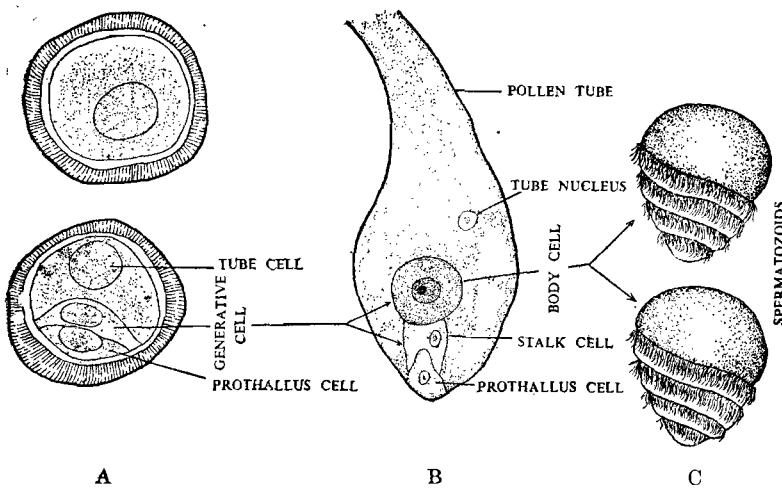

The **ovule** in longitudinal section (fig. 442A) shows: (a) a thick integument consisting of three layers, (b) a micropyle, (c) a pollen chamber, (d) a nucellus fused with the integument, (e) a female prothallus (often called the endosperm) which grows quickly after fertilization and forms the major part of the seed, (f) a few archegonia (2-8) borne by the female prothallus towards the micropyle, and (g) an archegonial chamber. Each archegonium (fig. 442B) is extremely reduced and consists of a short neck with two neck cells, a ventral canal cell represented only by a nucleus, and a venter filled with a large egg-cell with a distinct egg-nucleus in it.

Cycas. FIG. 442. A, an ovule in longitudinal section; I, II and III, outer, middle (stony) and inner layers of the integument; B, an archegonium with the egg-nucleus in the centre.

Pollination and Fertilization. Pollen grains are carried by the wind. Some of them fall on the micropyle in a drop of mucilage secreted by the latter. As the mucilage dries up, the pollen grains are drawn into the pollen-chamber. The tube-cell elongates into a long branched pollen-tube (fig. 443 B) which penetrates into the nucellus. The pollen-tube of *Cycas* is a sucking organ (haustorium) absorbing food from the nucellus. The generative cell divides into two—the stalk cell

and the body cell. The stalk cell is sterile and the body cell divides into two large top-shaped multiciliate male gametes (**spermatozoids**; fig. 443 C). The pollen-tube bursts at the apex and the spermatozoids are set free. They enter the archegonium and one of them fuses with the egg-nucleus. Fertilization is thus effected.

Cycas. FIG. 443. A, top, a pollen grain; bottom, male prothallus; B, pollen-tube (a portion); C, two spermatozoids.

Seed. The fertilized egg-cell grows into an embryo, and the ovule as a whole into a seed. The mature seed bears only one embryo with two cotyledons lying embedded in the prothallus (endosperm) which again is surrounded by the integument. The endosperm stores a considerable quantity of food for the embryo to be utilized at the time of germination.

PART VII ANGIOSPERMS

CHAPTER I *Principles and Systems of Classification*

Systematic Botany or Taxonomy. It deals with the description, identification and naming of plants, and their classification into different groups according to their resemblances and differences mainly in their morphological characteristics. So far as angiosperms or higher 'flowering' plants are concerned it has been estimated that over 199,000 species (dicotyledons—159,000 and monocotyledons—40,000) are already known to us, and many more are still being discovered and recorded. Thus plants are not only numerous but they are of varied types, and it is not possible to study them unless they are arranged in some orderly system. The object of systematic botany or taxonomy is to describe, name and classify plants in such a manner that their relationship with regard to their descent from a common ancestry may be easily brought out. The ultimate object of classification is to arrange plants in such a way as to give us an idea about the sequence of their evolution from simpler, earlier and more primitive types to more complex, more recent and more advanced types in different periods of the earth's history.

UNITS OF CLASSIFICATION

Species. By the term 'species' we mean a collection of individuals (plants or animals) which resemble one another in almost all important morphological characteristics—both vegetative and reproductive—so closely that they may be regarded as having been derived from the same parents. Thus all pea plants constitute a species. Similarly all banyan plants, all peepul plants, and all mango plants constitute different and distinct species. Occasionally, owing to variations in climatic or edaphic conditions, individuals of a species may show a certain amount of variations in form, size, colour and other minor characteristics. Such plants are said to form **varieties**. A species may consist of one or more varieties or none at all.

Genus. A genus is a collection of species which bear a close resemblance to one another in the morphological characters of the floral or reproductive parts. For example, banyan, peepul and fig are different species because they differ from one another in their vegetative characters such as the habit of the plant, the shape, size and surface of the leaf, etc. But these three species are allied because they resemble one another in their reproductive characters, namely, inflorescence, flower, fruit and seed. Therefore, banyan, peepul and fig come under the same genus, and that is *Ficus*.

Binomial Nomenclature. As mentioned on p. ix, this is the scientific method of naming species of plants or animals in two parts: the first refers to the genus and the second to the species. This system of naming plants or animals with a *binomial* was first introduced by Linnaeus in 1735 and the rules for its final adoption were drawn up by the International Botanical Congress held at Vienna in the year 1905. The name of the author who first described a species is also written in an abbreviated form after the name of the species, e.g. *Mangifera indica* Linn. Here Linn. refers to the author, Linnaeus, who first described the plant.

Family. A family is a group of genera which show general structural resemblances with one another mainly in their floral organs. Thus in the genera *Gossypium* (cotton), *Hibiscus* (China rose, lady's finger, etc.), *Thespesia* (Portia tree), *Sida* (B. BERELA ; H. BARIARA), *Malva* (mallow), *Althaea* (hollyhock), etc., we find free lateral stipules, epicalyx, twisted aestivation of corolla, monadelphous stamens, unilocular anthers, axile placentation, etc. So all the above-mentioned genera belong to the same family, and that is *Malvaceae*.

SYSTEMS OF CLASSIFICATION

There are two systems of classification—artificial and natural. In the **artificial system** only one or at most a few characters are selected arbitrarily and plants are arranged into groups according to such characters; as a result closely related plants are often placed in different groups, while quite different plants are often placed in the same group because of the presence or absence of a particular character. This system enables us to determine readily the names of plants but does not indicate the natural relationship that exists among the

individuals forming a group. It is like the manner of arrangement of words in a dictionary in which, except for the alphabetical order, adjacent words do not necessarily have any agreement with one another.

Linnaean System (1735). The best-known artificial system is the one compiled by Linnaeus and published by him in 1735. Linnaeus classified plants according to the characteristics of their reproductive organs, viz. stamens and carpels. According to this system plants are mainly divided into 24 classes: 23 of phanerogams and one of cryptogams. Phanerogams were further sub-divided into groups and sub-groups according to the following characteristics: unisexual or bisexual flowers, monoecious or dioecious plants, number of stamens, adhesion or cohesion of stamens, number and length of stamens, number of carpels, apocarpous or syncarpous pistil, etc.

In the **natural system** all the important characteristics are taken into consideration, and plants are classified according to their related characteristics. Thus according to their similarities and differences, mostly in their important morphological characteristics, plants are first classified into a few big groups. These are further divided and sub-divided into smaller and smaller groups until the smallest division is reached and that is a species. All modern systems of classification are natural and they supersede the artificial ones by the fact that they give us a true idea of the natural relationship existing between different plants and also of the sequence of their evolution from simpler to more complex types during different periods in the earth's history.

According to the natural system the plant kingdom has been divided into two *divisions*, viz. **cryptogams** or 'flowerless' plants (see Part V), and **phanerogams** or 'flowering' plants. Phanerogams have again been divided into two *sub-divisions*, viz. **gymnosperms** or naked-seeded plants (see Part VI), and **angiosperms** or closed-seeded plants. Angiosperms have further been divided into two *classes*, viz. **dicotyledons** and **monocotyledons** (see p. 327). The classes have been divided into sub-classes, series and *orders*; the last named into *families*; families again into *genera* and *species*; and sometimes species into varieties.

Bentham and Hooker's System (1862-83). The natural system that is in practice in India is that of Bentham and Hooker

and published by them during the above period. According to these authors the dicotyledons have been divided into three *sub-classes*, as follows :

1. **Polypetalae.** Both calyx and corolla present ; petals free ; stamens and carpels also usually present ; the former often indefinite and the latter apocarpous or syncarpous. Within the sub-class progress is indicated through polysepalous calyx to gamosepalous calyx, through indefinite number of stamens to definite number, and through hypogyny, perigyny and epigyny.

2. **Gamopetalae.** Both calyx and corolla present ; the latter gamopetalous ; stamens almost always definite and epipetalous ; carpels usually two but sometimes more, free or united ; ovary inferior or superior. This sub-class is also called Corolliflorae.

3. **Monochlamydeae.** Flowers incomplete ; either calyx or corolla absent, or sometimes both the whorls absent ; flowers generally unisexual. It usually includes the families which do not fall under the above two sub-classes.

According to Bentham and Hooker the monocotyledons are divided into seven *series*. A much simpler classification has been put forward by Vines in England. According to this author the monocotyledons are divided into three *sub-classes*, as follows :

1. **Petaloideae.** The perianth is usually petaloid.

2. **Spadiciflorae.** The inflorescence is a spadix, and is enclosed in one or more spathes.

3. **Glumiflorae.** The flower is enclosed in special bracts, called *glumes* (see p. 76).

Following the above scheme of classification any plant may be referred to its systematic position. Let us take BANI cotton.

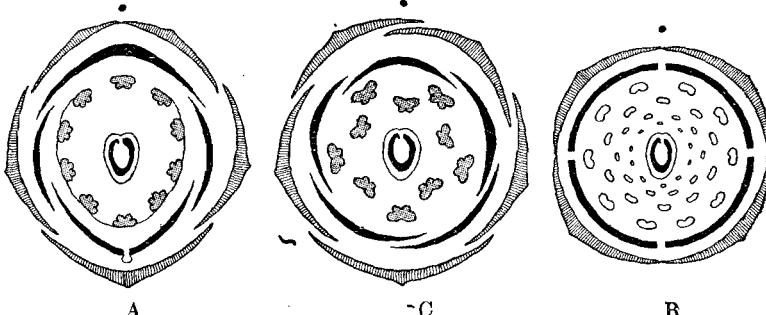

Division	Phanerogam
Sub-division	Angiosperm
Class	Dicotyledon
Sub-class	Polypetalae
Series	Thalamiflorae
Order	Malvales
Family	Malvaceae
Genus	<i>Gossypium</i>
Species	<i>indicum</i>

A plant is always denominated by the *generic* and *specific* name, with the name of the author at the end. Thus BANI cotton is *Gossypium indicum* Linn.

Differences between Dicotyledons and Monocotyledons.

	Dicotyledons	Monocotyledons
1. Embryo	with 2 cotyledons	with 1 cotyledon
2. Root	tap root	fibrous roots
3. Venation	reticulate	parallel
4. Flower	mostly pentamerous	trimerous
5. Vascular bundles	in stems collateral and open, in a ring, wedge-shaped, not very many; in roots radial, xylem bundles usually 2 to 6.	in stems collateral and closed, scattered, oval in shape, numerous; in root, radial, usually many
6. Secondary growth	present in both stem and root	absent (with but few exceptions).

Floral Diagram. The number of parts of a flower, their general structure, arrangement, aestivation, adhesion, cohesion, and position with respect to the mother axis may be represented by a diagram known as the **floral diagram**. The floral diagram is the ground plan of a flower. In the diagram the calyx lies outermost, the corolla internal to the calyx, the androecium in the middle, and the gynoecium in the centre. Adhesion and cohesion (see p. 95) of members of

Floral Diagrams. FIG. 444. A, Papilionaceae; B, Caesalpiniaceae; C, Mimosaceae.

floral whorls may also be shown by connecting the respective parts with lines; as, for example, fig. 444A shows that there are altogether ten stamens, of which nine are united into one bundle (cohesion) and the remaining one is free, while fig. 468 shows that petals and stamens are united (adhesion). The black dot on the top represents the position of the mother axis (not the pedicel) which bears the flower. The axis lies behind the flower and, therefore, the side of the flower nearest the axis is called the *posterior* side, and the other side away

from the axis, the *anterior* side. The floral characteristics of a species may be well represented by a floral diagram, while to represent a genus or a family more than one diagram may be necessary.

Floral Formula. The different whorls of a flower, their number, cohesion, adhesion and their relative position may be represented by a formula known as the **floral formula**. In the floral formula K stands for calyx, C for corolla, P for perianth, A for androecium, and G for gynoecium. The figures following the letters K, C, P, A and G indicate the number of parts of those whorls. Cohesion of a whorl is shown by enclosing the figure within brackets, and adhesion is shown by a line drawn on the top of the two whorls concerned. In the case of the gynoecium the position of the ovary is shown by a line drawn above or below G or the figure. If the ovary is superior the line should be below it, and if it is inferior the line should be on the top. Thus all the parts of a flower may be represented in a general way by the floral formula; the floral characters of a family may also be represented by one or more formulae, as follows:

Ranunculaceae : $K_5 C_5 A_\infty G_\infty$

Solanaceae : $K_{(5)} \overline{C_{(5)}} A_5 G_{(2)}$

Cruciferae : $K_{2+2} C_4 A_{2+4} G_{(2)}$

Labiatae : $K_{(5)} \overline{C_{(5)}} A_4 G_{(2)}$

Malvaceae : $K_{(5)} \overline{C_5 A_{(\infty)}} G_{(5-\infty)}$

Liliaceae : $P_{3+3} A_{3+3} G_{(3)}$

CHAPTER 2 Selected Families of Dicotyledons

Family 1—*Ranunculaceae* (1,200 sp.—157 sp. in India)

Habit: mostly perennial herbs or climbing shrubs. **Leaves**: simple, often palmately divided, sometimes compound, alternate (rarely opposite), often both radical and cauline, usually with sheathing base. **Inflorescence**: typically cymose (racemose in larkspur and aconite). **Flowers**: mostly regular except in larkspur and aconite, bisexual and hypogynous; sepals and petals in whorls; stamens and carpels typically spiral on the elongated thalamus. **Calyx**: sepals usually 5, sometimes more, free. **Corolla**: petals 5 or more, free, sometimes absent,

often with nectaries, imbricate; perianth leaves (when calyx and corolla not distinguishable) free and petaloid. **Androecium**: stamens numerous, free, spiral. **Gynoecium**: carpels usually numerous, sometimes few, free (apocarpous), spiral, with one or more ovules in each. **Fruit**: an etaerio of achenes or follicles, rarely a berry or capsule. **Seeds**: albuminous. *Floral formula—K₅C₅A∞ G∞.*

Examples. Useful plants: monk's hood or aconite (*Aconitum ferox*; H. BISH)—medicinal, tuberous roots containing a very poisonous alkaloid, black cumin (*Nigella sativa*; H.

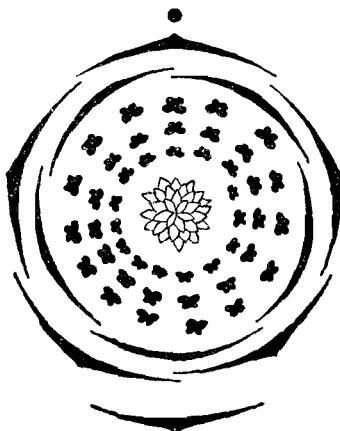

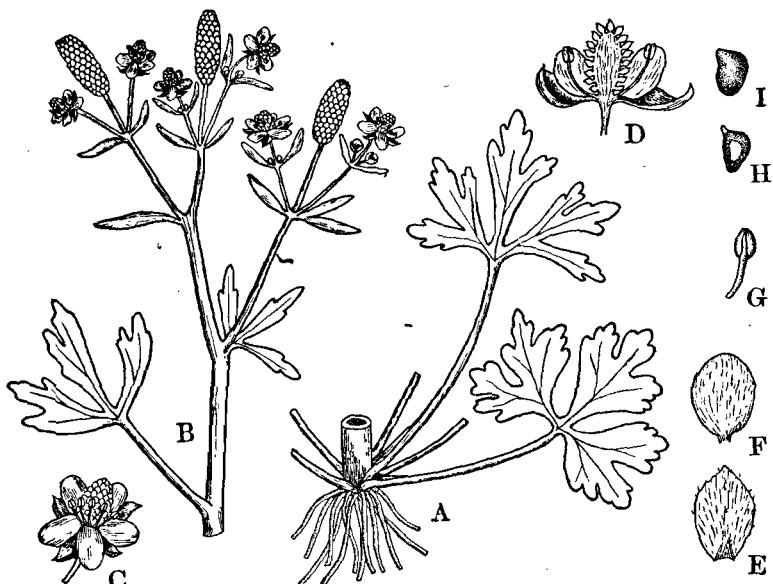

FIG. 445. Floral diagram of *Ranunculaceae*.

Ranunculaceae. FIG. 446. *Ranunculus sceleratus*. A, basal portion of the plant with leaves and roots; B, upper portion of the same with inflorescence; C, a flower; D, flower cut longitudinally; E, a sepal; F, a petal; G, a stamen; H, a carpel; and I, a fruit (achene).

KALA-JIRA)—seeds used as a condiment; **ornamental**: larkspur (*Delphinium*), wind flower (*Anemone*)—a small tuberous plant with woolly achenes for wind-dispersal, virgin's bower (*Clematis*)—a climbing shrub, buttercup (*Ranunculus*), etc.; **other common plants**: some species of *Ranunculus*, e.g. Indian buttercup (*Ranunculus sceleratus*) usually growing on river- and marsh-banks, water crowfoot (*R. aquatilis*) growing in water and showing heterophyly, etc., traveller's joy (*Naravelia*)—a climbing shrub, etc.

Family 2—*Cruciferae* (2,000 sp.—174 sp. in India)

Habit: herbs. **Leaves**: radical and caudine, simple, alternate, often lobed. **Inflorescence**: a raceme. **Flowers**: regular and cruciform, bisexual and complete, hypogynous, **Calyx**: sepals 2+2, free, in two whorls. **Corolla**: petals 4, free, in one whorl, valvate, cruciform, with distinct limb and claw. **Androecium**: stamens 6, in two whorls, 2 outer short and 4 inner long (tetrodynamous). **Gynoecium**: carpels (2), syncarpous; ovary superior; at first 1-celled, later 2-celled owing to the development of a false septum, called the *replum*, with often many ovules in each cell; placentation parietal. **Fruit**: a siliqua. **Seeds**: exalbuminous. **Floral formula**— $K_{2+2} C_4 A_{2+4} G_{(2)}$.

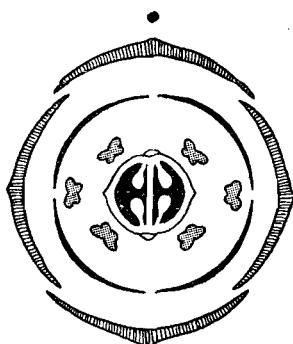

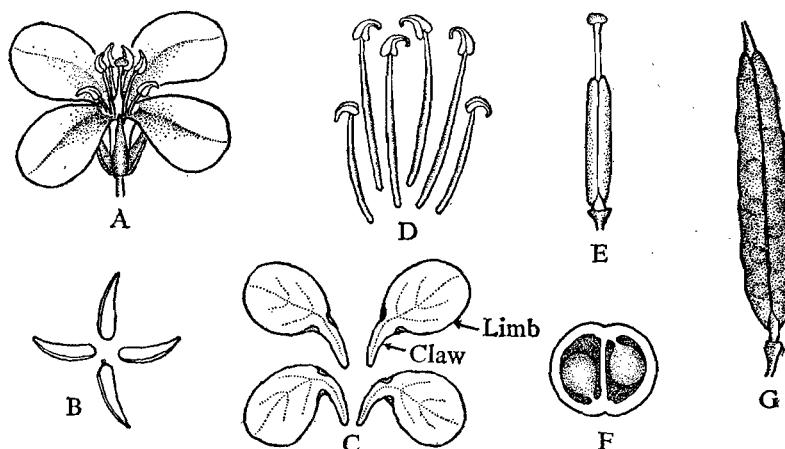

FIG. 447. Floral diagram of *Cruciferae*.

Examples. Useful plants: oils and condiments: mustard (*Brassica campestris*; H. SARSON) and *B. juncea* (H. RAI), rape (*B. napus*; H. TORIO), white mustard (*B. alba*), black mustard (*B. nigra*), etc.; **vegetables**: radish (*Raphanus sativus*), cabbage (*Brassica oleracea* var. *capitata*), cauliflower (*B. oleracea* var. *botrytis*), turnip (*B. rapa*), kohl-rabi or knol-kohl (*B. caulorapa*), *B. rugosa* (H. LAI), garden cress (*Lepidium sativum*; H. HALIM), etc.; **ornamental**: candytuft (*Iberis*; H. CHANDNI), wallflower (*Cheiranthus*), etc.; **other common plants**: *Nasturtium officinale*, *Eruca sativa*, shepherd's purse (*Capsella*), etc.

Description of Mustard Plant (*Brassica campestris*; fig. 448). A cultivated winter herb. **Leaves**: simple, alternate, radical and caudine, lyrate.

Inflorescence: a raceme. **Flowers**: regular, bisexual, hypogynous, cruciform, and bright yellow in colour. **Calyx**: sepals 2+2, free, imbricate. **Corolla**:

Cruciferae. FIG. 448. Mustard (*Brassica campestris*) flower. *A*, a flower—cruciform; *B*, calyx; *C*, corolla opened out; *D*, androecium showing tetradsynous stamens; *E*, gynoecium showing two carpels united; *F*, ovary in transection showing parietal placentation and replum; and *G*, a fruit—silique. [See also fig. 20].

petals 4, free, cruciform, valvate, with distinct claw and limb. **Androecium**: stamens 6, free, 4 inner long and 2 outer short (tetradsynous). **Gynoecium**: carpels (2), syncarpous; ovary divided into 2 chambers by the placental replum; placentation parietal. **Fruit**: a narrow, pod-like silique opening into 2 valves from base upwards. **Seeds**: many, small, globose and exalbuminous.

Family 3—*Malvaceae* (1,000 sp.

(—105 sp. in India)

Habit: herbs, shrubs and trees.

Leaves: simple, alternate and palmately-veined; stipules 2, free lateral. **Flowers**: regular, polypetalous, bisexual, hypogynous, copiously nucilaginous.

Calyx: sepals (5), united, with epicalyx (a whorl of bracteoles). **Corolla**: petals 5, free; aestivation twisted. **Androecium**: stamens ∞ , monadelphous, i.e. united into one bundle called staminal column or tube, epipetalous (staminal tube

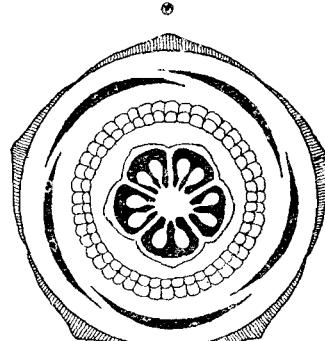

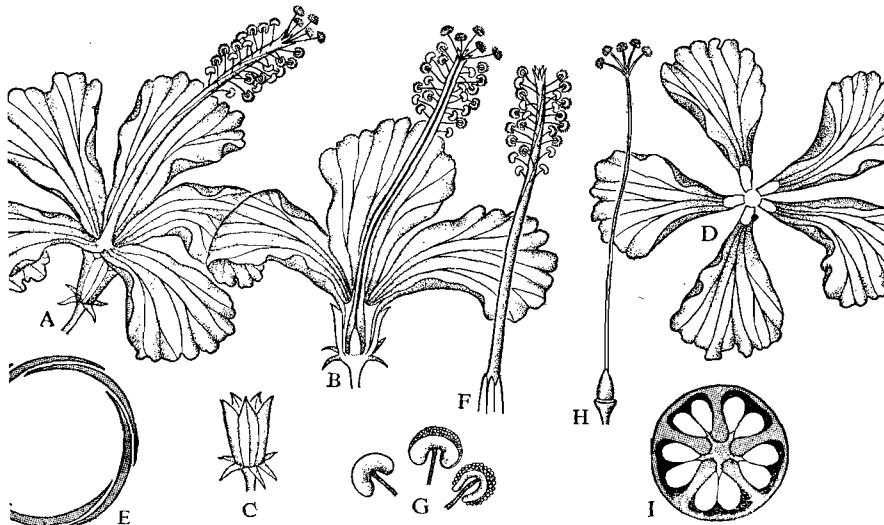

FIG. 449. Floral diagram of *Malvaceae*.

adnate to the petals at the base); anthers unilocular. **Gynoecium**: carpels (5 to ∞), usually (5), syncarpous; ovary superior, multilocular, with 1 to many ovules in each loculus; placentation axile; style passes through the staminal tube; stigmas free, as many as the carpels. **Fruit**: a capsule or sometimes a schizocarp. **Floral formula**: —K₍₅₎C₅A_(∞)G_(5-∞).

Malvaceae. FIG. 450. China rose (*Hibiscus rosa-sinensis*) flower. A, an entire flower; B, the same split open longitudinally showing the four whorls, more particularly the staminal column with the style passing through it; C, calyx with epicalyx; D, corolla opened out; E, twisted aestivation of corolla; F, androecium showing monadelphous stamens; G, one-celled anthers—young and mature (dehiscing); H, gynoecium showing five carpels united; and I, ovary in transection showing axile placentation.

Examples. **Useful plants**: *Gossypium* yields cotton of commerce, rozelle (*Hibiscus sabdariffa*; H. PATWA) and Deccan hemp (*H. cannabinus*; H. AMBARI or NALITA) are sources of strong fibres, lady's finger (*Hibiscus esculentus*)—green fruits used as a vegetable, mallow (*Malva*)—green leaves used as a vegetable, red or silk cotton tree (*Bombax*)¹ and white cotton tree (*Eriodendron*)²—cotton used for stuffing pillows and cushions and wood used for making tea chests, match boxes and match sticks, etc.; **ornamental**: several species of *Hibiscus*, e.g. shoe-flower or China rose (*H. rosa-sinensis*; H. GURHAL), *H. mutabilis* (H. CULIAJAIB), etc., and hollyhock (*Althaea*); **shade tree**: Portia tree (*Thespesia*); **other com-**

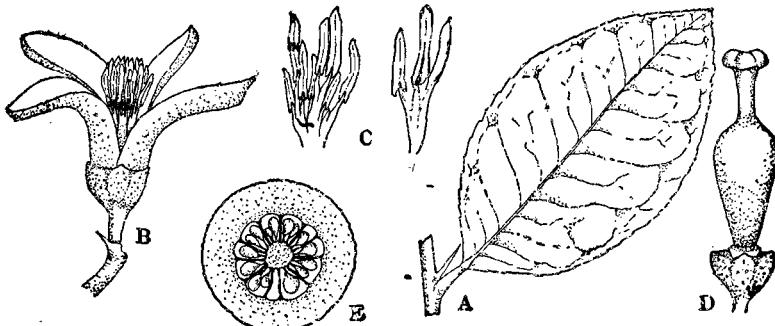

¹ and ² have now been separated into a new family *Bombacaceae*.

Common plants: *Sida cordifolia* (H. BARIARA), *Urena lobata* (H. BACHATA), *Hibiscus vitifolius* (H. BAN-KAPAS), Indian mallow (*Abutilon indicum*; H. KANGHI), *Malachra capitata* (H. BAN-BHINDI), *Malvastrum*—a weed of waste places.

Description of China Rose Plant (*Hibiscus rosa-sinensis*; fig. 450). A much-branched shrub. **Leaves:** simple, alternate, palmately 3-veined at the base, 8-10 cm. long, margin serrate, petiole long. **Flowers:** solitary and axillary on a long peduncle articulated to the pedicel, large and showy, red in colour, regular, bisexual, hypogynous; bracteoles 5 or more in the form of a whorl known as epicalyx. **Calyx:** 5-lobed. **Corolla:** petals 5, free; aestivation twisted clockwise or anticlockwise. **Androecium:** stamens numerous, united into a bundle (monadelphous), epipetalous, adnate to the petals at the base; anthers free, reniform, 1-lobed. **Gynoecium:** carpels (5), connate; style passing through the staminal column; stigmas 5; ovary 5-locular; placentation axile. **Fruit:** not formed; in other species of *Hibiscus* a loculicidal capsule.

Family 4—Rutaceae (1,200 sp.—66 sp. in India).

Habit: shrubs and trees (rarely herbs). **Leaves:** simple or compound, alternate or rarely opposite, gland-dotted. **Flowers:** regular, bisexual and hypogynous; disc below the ovary prominent. **Calyx:** sepals 4 or 5, free or slightly connate. **Corolla:** petals 4 or 5, free, imbricate. **Androecium:** stamens variable in number, generally twice as many as petals or sometimes as many as petals or numerous in *Citrus* and

Rutaceae. FIG. 451. Sour lime (*Citrus aurantifolia*). A, a leaf; B, a flower; C, stamens (polyadelphous); D, pistil (on a disc) and calyx; and E, section of ovary showing axile placentation.

Aegle, free or united in irregular bundles (polyadelphous). **Gynoecium:** carpels generally (4) or (5) or (∞) in *Citrus*, syn-carpous, or free at the base and united above, either sessile or seated on the disc; ovary usually 4- or 5-locular; multilocular

in *Citrus*, with axile placentation; ovules 2-∞ (rarely 1) in each loculus. **Fruit**: a berry, capsule or hesperidium (see fig. 225). **Seeds**: with or without endosperm. **Floral formula**— $K_{4-5}C_{4-5}A_{8, 10 \text{ or } \infty}G_{(4, 5 \text{ or } \infty)}$.

Examples. Useful Plants: *Citrus* (e.g. lime, lemon, orange, citron, pummelo or shaddock and grape fruit), wood-apple (*Aegle marmelos*; H. SIRIPHAL), elephant-apple (*Limonia acidissima*; H. KAITH), Chinese box (*Murraya exotica*; H. MAR-CHULA)—timber useful, curry leaf plant (*M. koenigii*; H. BAR-SUNGA)—leaves used for flavouring curries, *Peganum harmala* (H. HARMAL)—seeds yield Turkey-red, etc.; **other common plants**: *Glycosmis arborea* (H. BANNIMBU), *Clausena pentaphylla* (H. PANKARPUR), etc.

Common species of *Citrus*: sour lime (*C. aurantifolia*), sweet lime (*C. limetta*), lemon (*C. limon*), citron (*C. medica*), pummelo or shaddock (*C. grandis*), Mandarin orange (*C. reticulata*; H. SANGTRA), sweet orange (*C. sinensis*), grape fruit (*C. paradisi*), etc.

Family 5—*Leguminosae* (12,000 sp.—951 sp. in India).

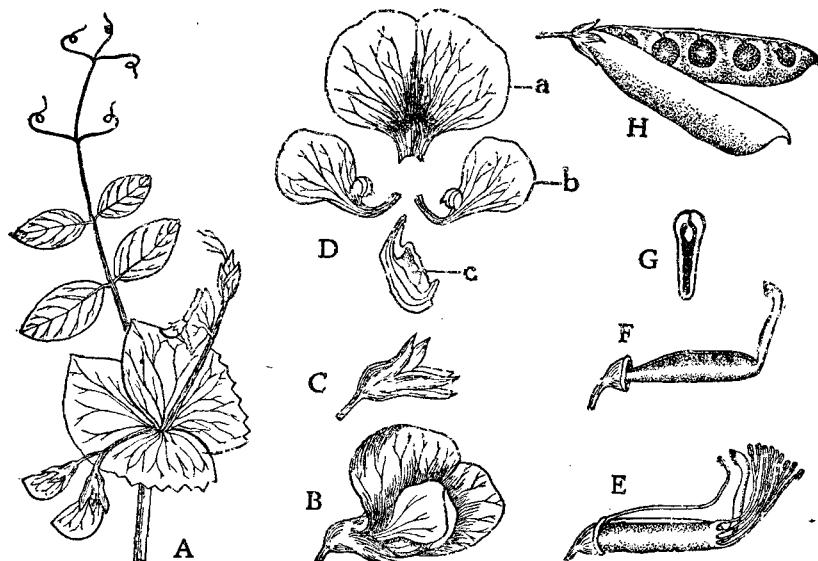

Habit: herbs, shrubs, trees and climbers. **Roots** of many species, particularly of *Papilionaceae*, have tubercles (see fig. 322). **Leaves**: alternate, pinnately compound, rarely simple, with a swollen leaf-base known as the pulvinus. **Flowers**: bisexual and complete, regular or zygomorphic, hypogynous or slightly perigynous. **Calyx**: sepals usually (5), sometimes (4). **Corolla**: petals usually 5, with the odd one posterior (towards the axis), sometimes 4, free or united. **Androecium**: stamens usually 10 or numerous, sometimes less than 10, free or united. **Gynoecium**: carpel 1; ovary 1-celled, with 1 to many ovules; placentation marginal. **Fruit**: a legume or pod.

This is the second biggest family among the dicotyledons (being only second to *Compositae*), and from economic standpoint this is probably the second most important family (ranking second to *Graminaceae*) because the pulses which are rich in proteins belong to it. Besides, the leguminous plants with root-nodules are natural fertilizers of the soil.

Primarily based on the characters of the corolla and the androecium *Leguminosae* has been divided into the following three sub-families.

(1) *Papilionaceae* (754 sp. in India). Herbs, shrubs, trees and climbers. **Leaves**: unipinnate, rarely simple. **Inflorescence**:

usually a raceme. **Flowers**: zygomorphic, polypetalous and papilionaceous. **Calyx**: sepals usually (5), gamosepalous. **Corolla**: petals usually 5, free, the posterior one largest; aestivation vexillary (see fig. 172). **Androecium**: stamens ten, diadelphous—(9)+1, rarely free or monadelphous, as in coral tree (*Erythrina*). **Floral formula**—K₍₅₎C₍₅₎A₍₉₎₊₁G₁. For floral diagram see p. 327.

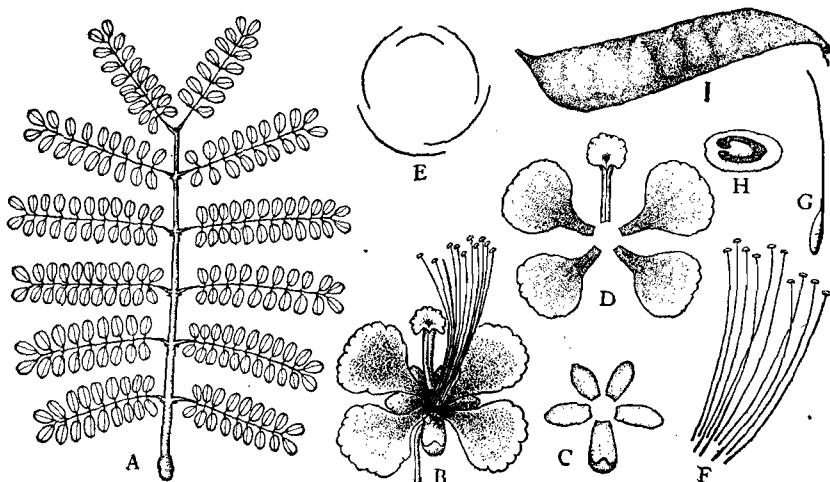

Papilionaceae. FIG. 452. Pea (*Pisum sativum*). *A*, a branch; *B*, a flower—papilionaceous (see also fig. 172); *C*, calyx; *D*, corolla—petals opened out (*a*, vexillum; *b*, wing; *c*, keel); *E*, stamens—(9)+1, and pistil; *F*, pistil—1 carpel (note the ovary, style and stigma); *G*, ovary in section showing marginal placentation; and *H*, a fruit—legume.

Examples. **Useful plants**: pulses (rich in proteins): pea (*Pisum sativum*; fig. 452), pigeon pea (*Cajanus cajan*), gram (*Cicer arietinum*), green gram (*Phaseolus aureus*), black gram (*P. mungo*), *Lathyrus sativus* (H. KHESARI), broad bean (*Vicia faba*), etc.; **vegetables**: country bean (*Dolichos lablab*), sword bean (*Canavalia gladiata*), cow pea (*Vigna sinensis*), French bean (*Phaseolus vulgaris*), etc.; **natural fertilizers**: *Sesbania cannabina*, *S. sesban*, lucerne or alfalfa (*Medicago sativa*)—also an excellent fodder, *Tephrosia candida*, etc.; **timber trees**: Indian redwood (*Dalbergia sissoo*) and Indian rosewood (*D. latifolia*); **ornamental**: sweet pea (*Lathyrus odoratus*), lupin (*Lupinus*), rattlewort (*Crotalaria sericea*), etc.; butterfly pea (*Clitoria ternatea*), coral tree (*Erythrina indica*), etc.; **other use-**

ful plants: groundnut (*Arachis hypogaea*; see fig. 353), Indian hemp (*Crotalaria juncea*), etc.; **other common plants**: Indian telegraph plant (*Desmodium gyrans*; see fig. 351), indigo (*Indigofera tinctoria*), cowage (*Mucuna pruriens*; H. KAWNACH), etc. (For description of pea flower see p. 103).

(2) *Caesalpiniaceae* (110 sp. in India). Shrubs and trees, rarely climbers or herbs. **Leaves**: unipinnate or bipinnate, rarely simple, as in camel's foot tree (*Bauhinia*). **Inflorescence**: commonly a raceme. **Flowers**: zygomorphic and polypetalous. **Calyx**: sepals usually 5, polysepalous (sometimes gamosepalous). **Corolla**: petals usually 5, free, imbricate, the upper smallest one always innermost. **Androecium**: stamens ten or fewer, free. **Floral formula**— $K_5C_5A_{10}G_1$. For floral diagram see p. 327.

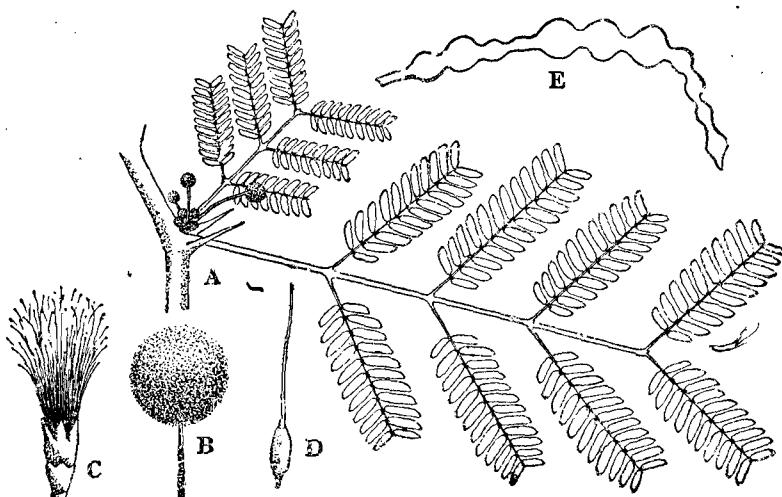

Caesalpiniaceae. FIG. 453. Dwarf gold mohur (*Caesalpinia pulcherrima*). A, a pinnately compound leaf; B, a flower; C, calyx; D, corolla—petals dissected out; E, aestivation (imbricate); F, stamens; G, pistil (one carpel); H, ovary in transection showing marginal placentation; I, a fruit.

Examples. Useful plants: tamarind (*Tamarindus indica*)—fruits widely used for sour preparations, Indian laburnum (*Cassia fistula*; H. AMALTASH)—heartwood very hard and durable, and flowers ornamental, etc.; **medicinal**: Indian senna (*Cassia angustifolia*; H. SANAKKAPAT), *Saraca indica* (H. SEETASOK), fever nut (*Caesalpinia bonduc*ella; (H. KAT-KARANGA), etc.; **dye**: sappan or Brazil wood (*Caesalpinia sappan*; H. BAKAM)—wood yields a valuable red dye extensively used

for dyeing silk and wool, starch coloured with this dye forms 'ABIR' used in 'HOLI' festival, and pods yield a high percentage of tannin; **ornamental**: camel's foot tree (*Bauhinia purpurea* and *B. variegata*; H. KACHNAR), gold mohur (*Delonix regia*; H. GULMOHR), dwarf gold mohur (*Caesalpinia pulcherrima*; H. GULETURA—fig. 453), etc.; **other common plants**: *Cassia sophera* (H. KASUNDA), *C. occidentalis* (H. BARA-KASUNDA), ring-worm shrub (*C. alata*; H. DAD-MARDAN), *C. tora* (H. CHAKUNDA), etc.

Description of Dwarf Gold Mohur Plant (fig. 453). A much-branched shrub. **Leaves**: bipinnately compound, leaflets many. **Inflorescence**: a raceme. **Flower**: zygomorphic, bisexual and hypogynous. **Calyx**: sepals 5, free, odd one outermost. **Corolla**: petals 5, free, spotted, odd one innermost and smallest, imbricate. **Androecium**: stamens 10, free; filaments slender and long. **Gynoecium**: carpel 1; ovary superior, 1-celled and many-ovuled. **Fruit**: flat pod, with many seeds.

(3) *Mimosaceae* (87 sp. in India). Shrubs and trees, sometimes herbs or woody climbers. **Leaves**: commonly bipinnate. **Inflorescence**: a head or a spike. **Flowers**: regular, often small and

Mimosaceae. FIG. 454. Gum tree (*Acacia arabica*). A, a branch with bipinnate compound leaves; B, an inflorescence (head); C, a flower; D, pistil (one carpel); and E, a fruit (lomentum).

aggregated in spherical heads. **Calyx**: sepals (5) or (4), generally gamosepalous, valvate. **Corolla**: petals (5) or (4), mostly gamopetalous; aestivation valvate. **Androecium**: stamens mostly numerous, sometimes 10, 8 or 4, free, sometimes united

at the base; pollen often united in small masses. **Floral formula**— $K_{(4-5)}C_{(4-5)}A_{\infty \text{ or few}}G_1$. For floral diagram see p. 327.

Description of *Accacia arabica* (fig. 454). A tree. **Leaves**: alternate, bipinnately compound, leaflets very small. Stipules modified into spines. **Inflorescence**: a globose head. **Flowers**: regular, bisexual and hypogynous, yellow in colour. **Calyx**: sepals (5) or (4), gamosepalous. **Corolla**: petals (5) or (4), gamopetalous; aestivation valvate. **Androecium**: stamens many, exserted, free or slightly connate at the base; pollen masses 2-4 in each cell. **Gynoecium**: carpel 1; ovary 1-celled and many ovuled. **Fruit**: a pod, septate, 10-15 cm. long.

Examples. Useful plants: catechu (*Acacia catechu*; H. KAITH) yields a kind of tannin called catechu which is obtained by boiling chips of heartwood, *A. arabica* (H. BABUL) and *A. senegal* yield gums, many species of *Acacia* are sources of tannin and fuel, *Albizia lebbek* (H. SIRISH)—a timber tree, *A. procera*—wood suitable for tea chests, many species of *Albizia* are sources of fuel, rain tree (*Enterolobium saman*)—planted as a shade tree, *Parkia*—a handsome avenue tree, etc.; **other common plants**: sensitive plant (*Mimosa pudica*; H. LAJWANTI or CHUIMUI), *Pithecellobium dulce* (H. DEKANI-BABUL), nicker been (*Entada scandens*; H. GILA) and *Prosopis spicigera* (H. SHOMI).

Family 6—Rosaceae (2,000 sp.—244 sp. in India)

Habit: herbs, shrubs, trees and climbers. **Leaves**: simple or compound, alternate; stipules 2, often adnate to the petiole. **Inflorescence**: flowers solitary or in terminal cymes or racemes. **Flowers** (see fig. 191C): regular, bisexual, rosaceous, typically perigynous with the receptacle hollowed and cup-shaped, rarely epigynous (as in apple and pear). Disc often present in the form of a ring. **Calyx**: sepals 5, adnate to the receptacle, lobes free, sometimes with *epicalyx*. **Corolla**: petals 5 (many in cultivated roses), free, usually imbricate, alternating with the sepals, usually white or pink. **Androecium**: stamens numerous, incurved in the bud, rarely few. **Gynoecium**: carpels usually numerous, free (as in rose) or sometimes (5), united (as in apple and pear) or only 1 (as in plum and peach); ovary unilocular or 5-locular in syncarpous, pistil, with 1, 2 or 3 ovules in each loculus; ovules anatropous and pendulous. **Fruit**: varying—drupe, follicle, berry, achene or pome (see fig. 224). **Seeds**: exalbuminous. **Floral formula**— $K_5C_5A_{\infty}G_{\infty,(5) \text{ or } 1}$.

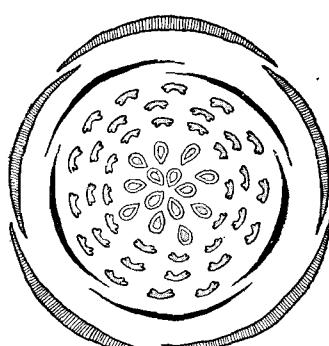

FIG. 455. Floral diagram of Rosaceae.

Economically this is an important family. Otto of rose is mostly obtained from *Rosa damascena* and *R. centifolia*; there are many fleshy edible fruits, e.g. plum, peach, prune, apricot, strawberry, apple, pear, etc., and several varieties of rose are ornamental garden plants.

Examples. Rose (*Rosa*) with 150 species, e.g. dog rose (*R. involucrata*) with five petals, wild rose (*R. gigantea*), Damask or Bussora rose (*R. damascena* and *R. centifolia*), musk rose (*R. moschata*), *R. indica*, *R. alba*, etc., loquat (*Eriobotrya japonica*), plum (*Prunus communis*), peach (*P. persica*), almond (*P. amygdalus*), strawberry (*Fragaria vesca*), wild strawberry (*F. indica*), apple (*Malus sylvestris*), pear (*Pyrus communis* and *P. pyrifolia*), silverweed (*Potentilla fulgens*), raspberry (*Rubus idaeus*), wild raspberry (*R. moluccanum*), etc.

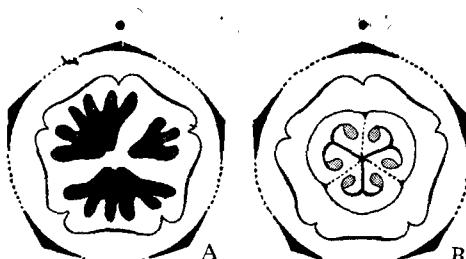

Family 7—Cucurbitaceae (800 sp.—84 sp. in India)

Habit: tendril climbers; tendrils simple or branched. **Leaves:** simple, alternate, broad and palmately veined. **Flowers:** regular, unisexual, epigynous and monoecious or dioecious. **Calyx:** sepals (5), united, often deeply 5-lobed. **Corolla:** petals (5), united, often deeply 5-lobed, imbricate; inserted on the calyx-tube.

Male Flowers: **androecium**: stamens usually 3, united in a pair, or 5, united in 2 pairs, the odd one remaining free; the stamens may unite by their whole length or by their anthers only; each anther 1- or 2-lobed; paired ones 2- or 4-lobed; anther-lobes sinuous, i.e. twisted like S. **Floral formula**— $K_{(5)} C_{(5)} A_{3 \text{ or } 5}$.

Female Flowers: **gynoecium**: carpels (3), syncarpous; ovary inferior, unilocular and placentation parietal but often the

FIG. 456.
Floral diagrams
of Cucurbitaceae.
A, male flower;
B, female flower.

placentae intrude far into the chamber of the ovary making the latter falsely trilocular; ovules many; style 1; stigmas 3 which are often forked. **Fruit:** a pepo. **Floral formula**— $K_{(5)} C_{(5)} G_{(3)}$.

Plants of this family are mostly used as vegetables, a few yield delicious summer fruits, and a few are medicinal.

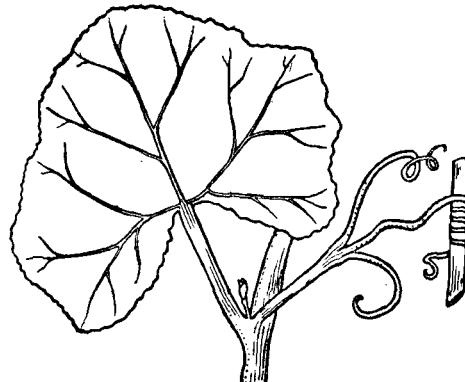

FIG. 457

Cucurbitaceae. FIG. 457. Gourd (*Cucurbita pepo*). Portion of a branch with a leaf and a tendril. FIG. 458. Male flower of the same. A, one stamen; B, two stamens united together.

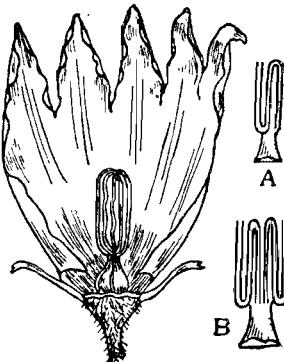

FIG. 458

Examples. Vegetables: sweet gourd or musk melon (*Cucurbita moschata*), pumpkin or vegetable marrow (*C. pepo*), snake gourd (*Trichosanthes anguina*), *T. dioica* (H. PARWAL), bitter gourds (*Momordica charantia*; H. KARELI) and *M. cochinchinensis*; H. CHATTHAI), bottle gourd (*Lagenaria siceraria*), ash or wax gourd (*Benincasa cerifera*; H. PETHA), ribbed gourd (*Luffa acutangula*), bath sponge or loofah (*L. cylindrica*), etc.; fruits: water melon (*Citrullus vulgaris*), melon (*Cucumis melo*) and cucumber (*C. sativus*); medicinal: colocynth (*Citrullus colocynthis*; H. INDRAYAN), *Coccinia cordifolia* (H. BHIMBA) and *Bryonia*.

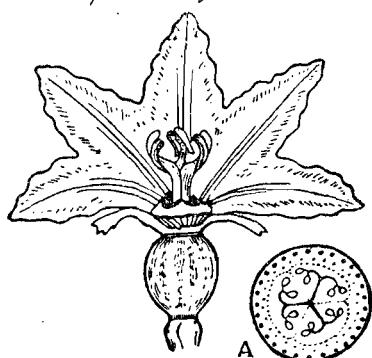

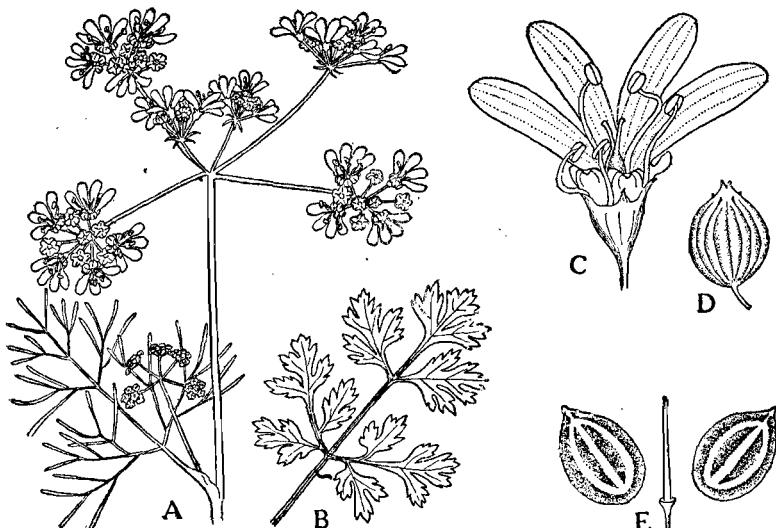

FIG. 459. Female flower of gourd (*Cucurbita pepo*). A, ovary in transverse section showing placentation.

FIG. 459. Female flower of gourd (*Cucurbita pepo*). A, ovary in transverse section showing placentation. **Fruit:** a large fleshy pepo. **Seeds:** many, exalbuminous, compressed.

Description of Gourd Plant (*Cucurbita pepo*; figs. 457-9). A large climbing herb, hairy all over; tendril opposite leaf, 2- to 4-fid. **Leaves:** broad, long-petioled, palmately veined. **Flowers:** solitary, large, yellow in colour, regular, unisexual (monoecious). **Calyx:** sepals (5), connate; lobes linear or leafy. **Corolla:** petals (5), connate, campanulate. **In male flowers:** **androecium:** stamens 3, united in a pair, the odd one remaining free; anthers united, one 1-celled and two 2-celled, sinuous. **In female flowers:** **gynoecium:** carpels (3), syncarpous; ovary inferior, 1-celled; placentation parietal; ovules many; stigmas 3, each forked. **Fruit:** a large fleshy pepo. **Seeds:** many, exalbuminous, compressed.

Family 8—Umbelliferae (2,700 sp.—176 sp. in India)

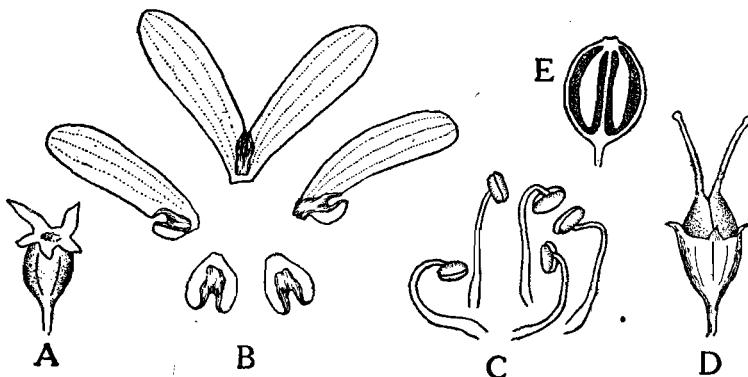

Habit: herbs (rarely shrubs); stem usually fistular. **Leaves:** alternate, simple, entire, lobed or much dissected, or sometimes decompound; petiole usually sheathing at the base. **Inflorescence:** an umbel, usually compound, sometimes simple, with an involucle of bracts. **Flowers:** regular (actinomorphic) or sometimes zygomorphic, epigynous, bisexual or polygamous, outer flowers sometimes rayed. **Calyx:** sepals 5, free, adnate to the ovary, often considerably reduced in size. **Corolla:** petals 5, free adnate to the ovary, sometimes unequal, margin often incurved, valvate or imbricate. **Androecium:** stamens 5, free, alternating with the petals, epigyn-

Umbelliferae. FIG. 460. Coriander (*Coriandrum*). *A*, a branch with leaf and compound umbels; *B*, a lower leaf; *C*, a flower; *D*, a fruit; and *E*, a fruit split into two mericarps, and the carpophore.

ous; filaments bent inwards in the bud, anthers introrse. **Gynoecium:** carpels (2), syncarpous; ovary inferior, 2-celled, crowned by a 2-lobed epigynous disc with two free styles arising from it; ovules 2, solitary in each cell, pendulous. **Fruit:** a cremocarp consisting of two indehiscent carpels laterally or dorsally compressed, breaking up into two parts, called *mericarps*, each attached to a slender, often forked axis (*carpophore*); each mericarp usually shows five longitudinal ridges and oil-canals (*vittae*) in the furrows. **Seeds:** 2, solitary in each carpel, albuminous. *Floral formula*— $K_5C_5A_5\bar{G}_{(2)}$.

Examples. **Condiments and spices:** coriander (*Coriandrum sativum*), anise or fennel (*Foeniculum vulgare*), *Carum copticum* (H. AJOWAN), caraway (*C. curvi*; H. SHIAJIRA), cumin (*Cuminum cyminum*; H. SAFEDJIRA), dill (*Peucedanum graveolens*; H. SOWA), etc.; **vegetables:** carrot (*Daucus carota*), parsnip (*Pastinaca sativa*), celery (*Apium graveolens*),

Umbelliferae (contd.). FIG. 461. A, calyx with inferior ovary; B, petals dissected out; C, stamens dissected out; D, pistil with calyx and 2-lobed disc.; and E, ovary in longitudinal section.

etc.; **medicinal:** asafoetida (*Ferula foetida*)—commercial HING is obtained from the roots (also used as a condiment), Indian pennywort (*Centella asiatica*), *Carum copticum* (also used as a condiment), etc.; **other common plants:** wild coriander (*Eryngium foetidum*), *Centella rotundifolia*—a common weed among grasses, etc.

Family 9—Rubiaceae (5,500 sp.—489 sp. in India)

Habit: herbs, shrubs, trees and twiners, sometimes thorny. **Leaves:** simple, opposite (decussate) or whorled with interpetiolar (sometimes intrapetiolar) stipules. **Inflorescence:** typically cymose. **Flowers:** regular, bisexual, epigynous. **Calyx:** sepals usually (4), sometimes (5), gamosepalous. **Corolla:** petals usually (4), sometimes (5), gamopetalous, generally rotate. **Androecium:** stamens as many as petals, inserted on the tube or mouth of the corolla, epipetalous, alternating with the corolla-lobes. **Gynoecium:** carpels (2), syncarpous; ovary inferior, usually 2-locular, with 1-∞ ovules in each loculus; disc present, often annular. **Fruit:** a berry or drupe or capsule. **Floral formula**— $K_{(4-5)} C_{(4-5)} A_{4-5} G_{(2)}$.

Examples. **Useful plants:** **medicinal:** *Cinchona* yields quinine, ipecac yields emetine, *Paederia foetida* (H. GANDHALI), etc.; **ornamental:** *Ixora coccinea*, *Gardenia florida* (H. GANDHARAJ), *Anthocephalus cadamba* (H. KADAM), *Adina cordifolia* (H. KELIKADAM), *Mussaenda* (see fig. 162), etc.; **dye:** madder (*Rubia cordifolia*; H. MANJISTHA); **beverage:** coffee (*Coffea arabica* and *C. robusta*); **other common plants:** *Coffea bengalensis*, Olden-

landia Corymbosa (H. KHETPAPRA), *O. diffusa*, *Dentella repens*—all growing as weeds, *Vangueria spinosa* (H. MOINA)—a thorny shrub, etc.

Family 10—Compositae (14,100 sp.—674 in India)

Habit: herbs and shrubs. **Leaves:** simple, alternate or opposite, rarely compound. **Inflorescence:** a head (or capitulum), with an involucre of bracts. **Flowers** (florets) are of two kinds—the central ones (called *disc florets*) are tubular, and the marginal ones (called *ray florets*) are ligulate; sometimes all florets are of one kind, either tubular or ligulate.

Disc Florets: regular, tubular, bisexual and epigynous, each usually in the axil of a bracteole.

Calyx: often modified into pappus, or into scales, or absent.

Corolla: petals (5), gamopetalous, tubular. **Androecium:** stamens 5, epipetalous, filaments free but anthers united (syngenesious).

Gynoecium: carpels (2), syncarpous, ovary inferior, 1-celled, with one basal ovule; style 1; stigmas 2. **Fruit:** a cypsela. **Floral formula—**

$K\ pappus$ or o $C_{(5)} A_{(5)} G_{(2)}$.

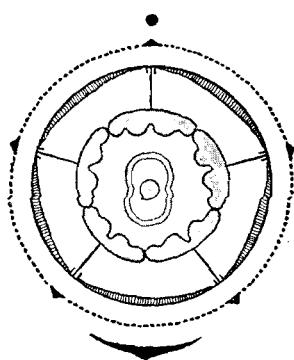

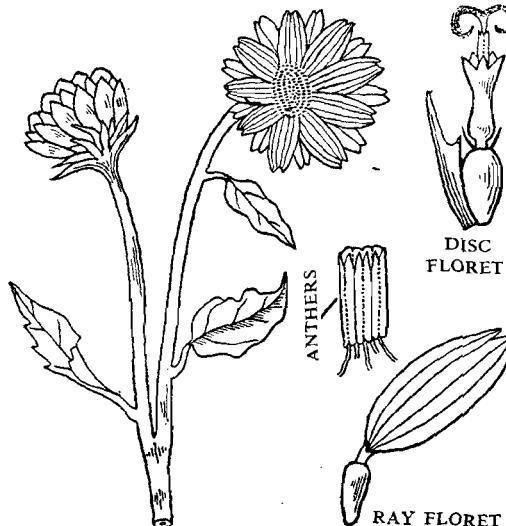

FIG. 462. Floral diagram of
Compositae (disc floret).

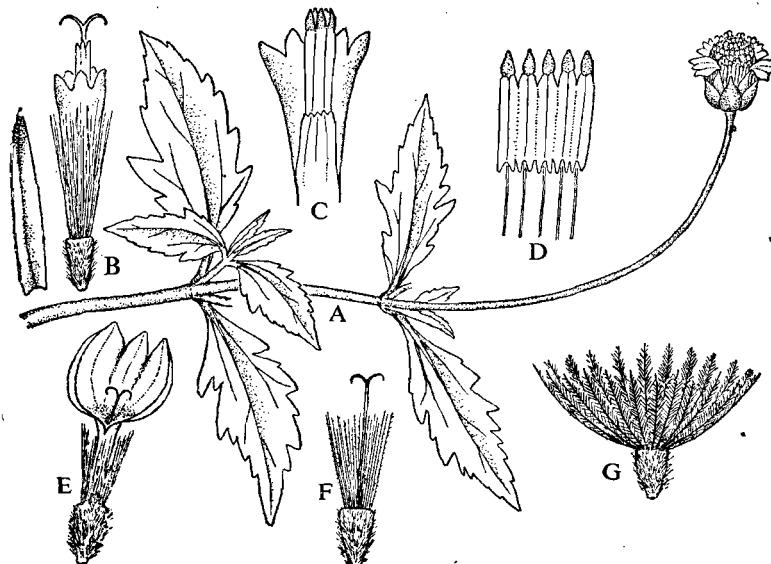

Compositae.
FIG. 463.
Sunflower
(*Helianthus annuus*).
Branch with two heads;
disc floret (bisexual);
anthers (syngenesious);
and ray floret (neuter
or female).

Ray Florets: zygomorphic, ligulate, unisexual (female) or sometimes neuter, as in sunflower, and epigynous, each usually in the axil of a bracteole. **Calyx:** as in disc floret. **Corolla:** petals (5), gamopetalous, ligulate (strap-shaped). **Gynoecium:** as in the disc floret. **Fruit:** the same. **Floral formula—**
 $K\ pappus$ or $o\ C_{(5)} A_0 G_{(2)}$.

Examples. **Useful plants:** **ornamental:** sunflower (*Helianthus annuus*), marigold (*Tagetes patula*), *Chrysanthemum*, *Dahlia*, *Zinnia*, *Cosmos*, etc.; **vegetables:** chicory (H. KASNI), endive, lettuce (*Lactuca sativa*), *Enhydra fluctuans* (H. HARUCH), etc.; **oils:** safflower (*Carthamus tinctorius*; H. KUSAM), etc.; **medicinal:** Indian wormwood (*Artemisia vulgaris*; H. NAGDUNA), santolin (*A. cina*), *Eupatorium ayapana*, *Wedelia calendulacea* (H. BHANGRA), etc.; **insecticides:** a few species of *Chrysanthemum* (*Pyrethrum*); **other common plants**—*Tridax procumbens* (fig. 464), *Eclipta alba* (H. SAFED BHANGRA), *Eupatorium odoratum*, *Blumea lacera* (H. KOKRONDA), etc.

Description of Sunflower Plant (*Helianthus annuus*; fig. 463). Sunflower is an annual garden herb. **Leaves:** simple, opposite, often the upper ones

Compositae. FIG. 464. *Tridax procumbens*. A, a branch with a head; B, a disc floret with a bracteole; C, corolla (split open) and epipetalous stamens; D, syngenesious stamens (split open); E, a ray floret; F, pistil and pappus; and G, a fruit (cypsela) with pappus (parachute mechanism).

alternate. **Inflorescence**: head or capitulum (large in some cases), with an involucre of bracts, usually 3-seriate. **Flowers**: central florets, called disc florets, are tubular and bisexual, and marginal florets, called ray florets, are zygomorphic, ligulate and neuter. **Disc florets**—regular, tubular, bisexual and epigynous. **Calyx**: modified into two scales. **Corolla**: gamopetalous, 5-lobed. **Androecium**: stamens 5, epipetalous and syngenesious, forming a tube around the style. **Gynoecium**: carpels (2), syncarpous; ovary inferior, 1-celled, with one basal ovule; style 1, but stigmas 2. **Fruit**: a cypsela. **Ray florets**—zygomorphic, ligulate, neuter or female and epigynous. **Calyx**: as in disc florets or absent. **Corolla**: ligulate, 5-lobed. **Stamens**: absent. **Gynoecium**: as in disc florets, but style and stigmas often absent making the flower neuter.

Family 11—Apocynaceae (1,400 sp.—67 in India)

Habit: herbs, shrubs, trees, twiners and lianes; with latex; bicollateral bundles. **Leaves**: simple, opposite or whorled, rarely alternate. **Flowers**: regular, bisexual and hypogynous, in cymes. **Calyx**: sepals (5), rarely (4), gamosepalous, imbricate. **Corolla**: petals (5), rarely (4), gamopetalous twisted. **Androecium**: stamens 5, rarely 4, epipetalous, included within the corolla-tube; anthers usually connate around the stigma. Disc present, ring-like or glandular. **Gynoecium**: carpels 2 or (2), apocarpous or syncarpous; ovary superior, 1- or 2-locular, with 2-∞ ovules in each. **Fruit**: a pair of follicles, or berry or drupe. **Seeds**: often with a crown of long silky hairs, mostly endospermic. **Floral formula**— $K_{(5)}\ C_{(5)}\ A_5\ G_2$ or (2).

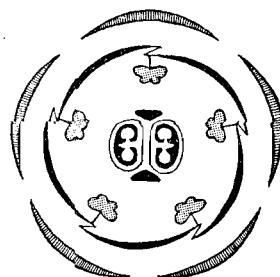

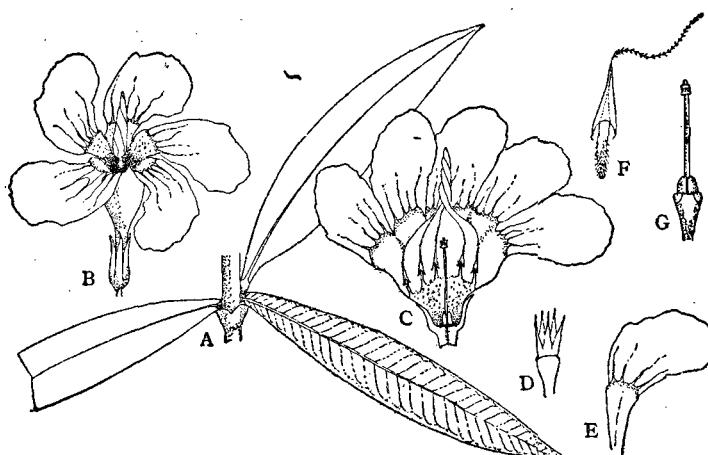

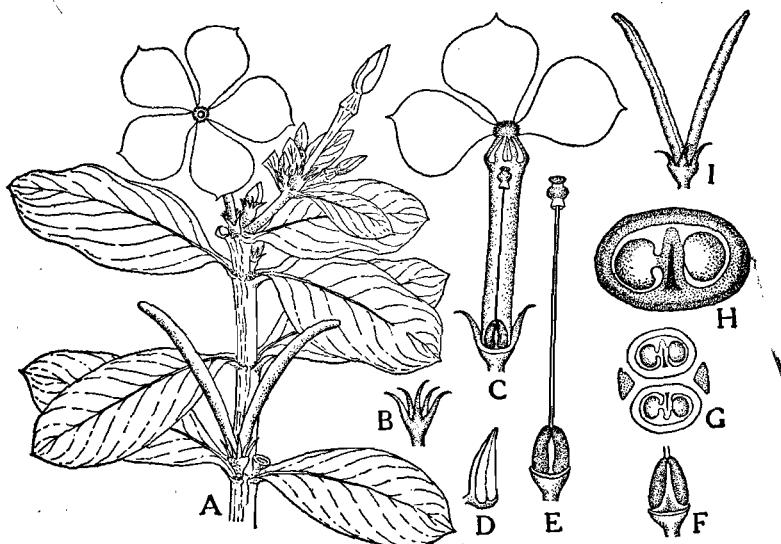

FIG. 465. Floral diagram of *Apocynaceae*.

Apocynaceae. FIG. 466A. Oleander (*Nerium odoratum*). A, a whorl of leaves; B, a flower; C, a flower opened out; D, calyx; E, a petal; F, a stamen (connective with hairy appendage); and G, pistil.

Examples. Useful plants : medicinal : *Rauwolfia serpentina* (H. SARPGAND), *Holarrhena antidysenterica* (H. KARCHI), yellow oleander (*Thevetia peruviana*; H. PILA-KANER)—seeds very poisonous, devil tree (*Alstonia scholaris*; H. CHATIUM), etc.; fruits : *Carissa carandas* (H. KARONDA)—a thorny shrub; ornamental : periwinkle (*Vinca rosea*; H. SADABAHAR—fig. 466B), oleander (*Nerium odoratum*; H. KANER—fig. 466A), *Ervatamia divaricata* (H. CHANDNI), pagoda or life tree (*Plumeria rubra*; H. GOLAINCHI), *Aganosma caryophyllata* (H. MALLI), *Allamanda*, etc.

*Apocynaceae. FIG. 466B. Periwinkle (*Vinca rosea*). A, a branch; B, calyx; C, a flower split longitudinally; D, a stamen; E, pistil; F, ovaries with disc; G, ovaries with disc (of two glands) in section; H, one ovary in section; and I, a pair of follicles.*

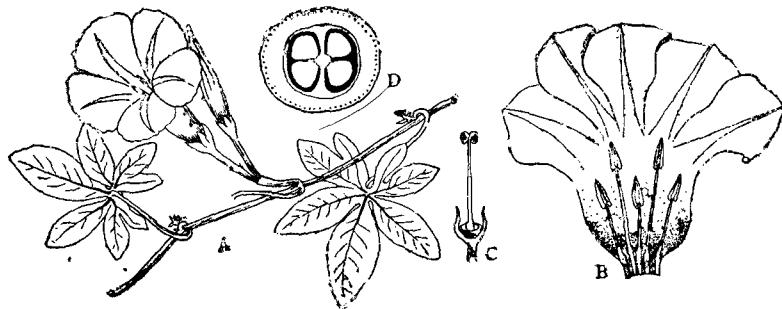

Description of Periwinkle Plant (*Vinca rosea*; fig. 466B). An erect or procumbent herb or undershrub containing latex. **Leaves**: opposite, 4-5 cm. long, oval or oblong in shape. **Flowers**: axillary, solitary, white or rosy, regular, bisexual, hypogynous, rotate with distinct tube and limb. **Calyx**: sepals (5), connate. **Corolla**: petals (5), connate, 5-lobed, with twisted aestivation. **Androecium**: stamens 5, inserted within the corolla-tube and adnate to it; filaments very short or absent. Disc of 2 large glands. **Gynoecium**: carpels 2, with 2 free ovaries but 1 style and 1 stigma, annulated. **Fruits** of 2 slender, erect follicles.

Family 12—*Convolvulaceae* (1,100 sp.—157 sp. in India)

Habit: mostly twiners. **Leaves**: simple, alternate and exstipulate. **Inflorescence**: cymose. **Flowers**: regular, bisexual, hypogynous, often large and showy. **Sepals**: 5, usually free, imbricate and persistent. **Petals**: (5), united, funnel-shaped, twisted in bud, sometimes imbricate. **Stamens**: 5, epipetalous, alternating with the petals. **Carpels**: (2), rarely more, connate; ovary superior, with a disc at the base, 2-celled, with 2 ovules in each cell, or

sometimes 4-celled with 1 ovule in each cell; placentation axile. **Fruit**: a berry or a capsule. **Floral formula**— $K_5 \overline{C}_{(5)} A_5 \underline{G}_{(2)}$.

Examples. **Useful plants**: **vegetables**: sweet potato (*Batatas edulis*; H. SHAKARKAND), and water bindweed (*Ipomoea reptans*; H. KALMI-SAK); **medicinal**: *Ipomoea paniculata* (H. BHUI-KUMRA), and Indian jalap (*Opperculina turpethum*; H. TARBUK); **ornamental**: morning glory (*I. purpurea*), railway creeper (*I. palmata*), moon flower (*I. grandiflora*), *Quamoclit pin-nata* (H. KAMLATI), *Convolvulus*, etc.; **other common plants**: dodder (*Cus-cuta reflexa*; H. AKASH-BEL—see fig. 13). *Evolvulus alsinoides*—a very common prostrate weed with white flowers in grassy places, etc.

Convolvulaceae. FIG. 467. Railway creeper (*Ipomoea palmata*). A, a branch; B, corolla with epipetalous stamens (opened out); C, pistil; and D, section of ovary showing axile placentation.

Family 13—Solanaceae (2,000 sp.—58 sp. in India)

Habit: herbs and shrubs. **Leaves**: simple, sometimes pinnate as in tomato, alternate. **Flowers**: regular, bisexual hypogynous.

Calyx: sepals (5), united, persistent. **Corolla**: petals (5), united, usually funnel- or cup-shaped, valvate or twisted in bud. **Androecium**: stamens 5, epipetalous, alternating with the corolla-lobes; anthers apparently connate. **Gynoecium**: carpels (2), syncarpous; ovary superior; 2-celled or sometimes 4-celled owing to the development of false septa, as in tomato and thorn-apple,

with many ovules in each; placentation axile. **Fruit**: a berry or capsule with many seeds. **Floral formula**— $K_{(5)} \overline{C}_{(5)} A_5 \underline{G}_{(2)}$.

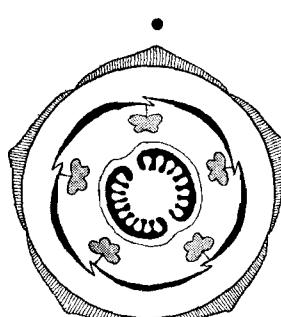

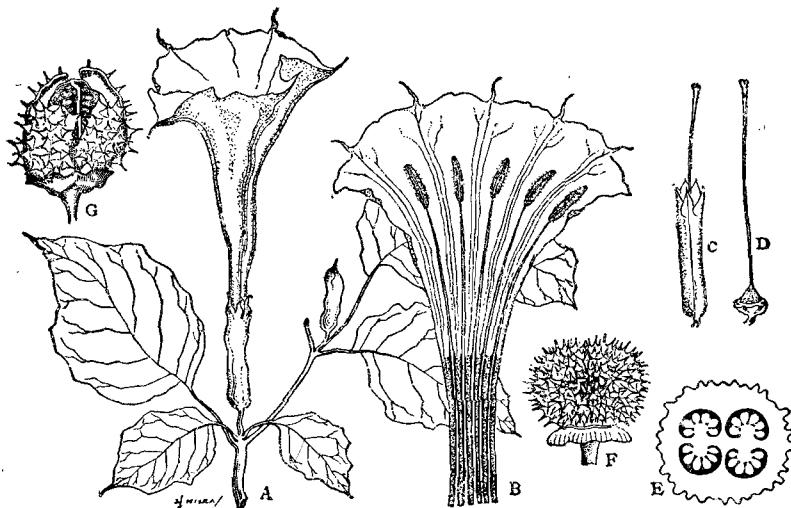

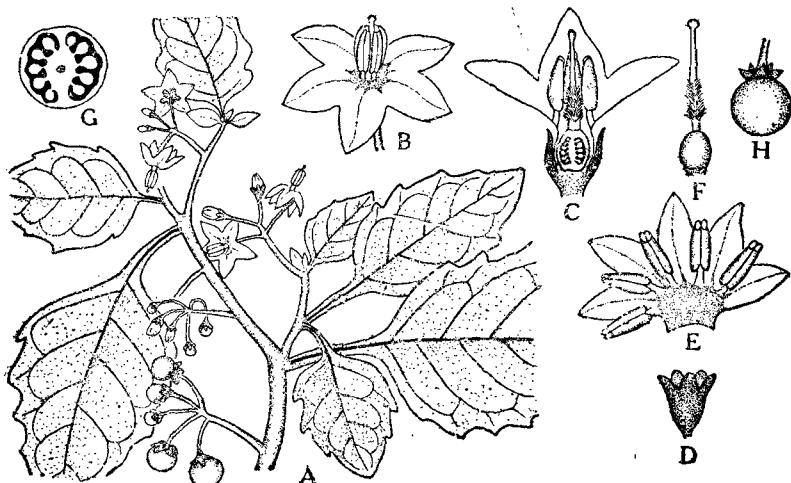

FIG. 468. Floral diagram of *Solanaceae*.

Examples. *Solanum* with 1,200 species is the largest genus of the family. **Useful plants:** vegetables: potato (*Solanum tuberosum*), brinjal (*S. melongena*), tomato (*Lycopersicum esculentum*);

Solanaceae. FIG. 469. Thorn-apple (*Datura fastuosa*). A, a leafy branch with a flower; B, corolla (opened out) with epipetalous stamens; C, pistil and persistent calyx; D, pistil; E, section of ovary showing four chambers (varying from 3 to 5); F, a young fruit; and G, a mature fruit (capsule).

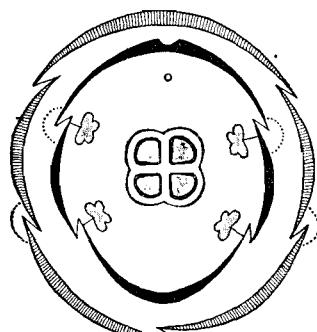

Solanaceae. FIG. 470. Black nightshade (*Solanum nigrum*). A, a branch; B, a flower; C, a flower cut longitudinally; D, calyx; E, corolla with epipetalous stamens; F, pistil; G, ovary in transverse section showing axile placentation; and H, a fruit (berry).

lentum), etc.; **medicinal**: deadly nightshade (*Atropa belladonna*), thorn-apple (*Datura fastuosa*; fig. 469)—seeds very poisonous, bittersweet (*Solanum dulcamara*; H. MITHABISH), *S. xanthocarpum* (H. KATITA), *S. indicum* (H. BIRHATTA), *Withania somnifera* (H. ASGAND), etc.; **narcotic**: tobacco (*Nicotiana tabacum*)—tobacco of commerce and also a source of nicotine—an insecticide, and henbane (*Hyoscyamus niger*)—narcotic and medicinal; **fruits**: gooseberry (*Physalis peruviana*; H. RASBHARI) and tomato; **ornamental**: *Petunia* and queen of the night (*Cestrum nocturnum*; H. RAT-KI-RANI), etc.,; **other common plants**: black nightshade (*Solanum nigrum*; H. GURKAMAI—fig. 470), wild gooseberry (*Physalis minima*) and wild tobacco (*Nicotiana plumbaginifolia*).

Family 14—Labiatae (3,000 sp.—391 sp. in India)

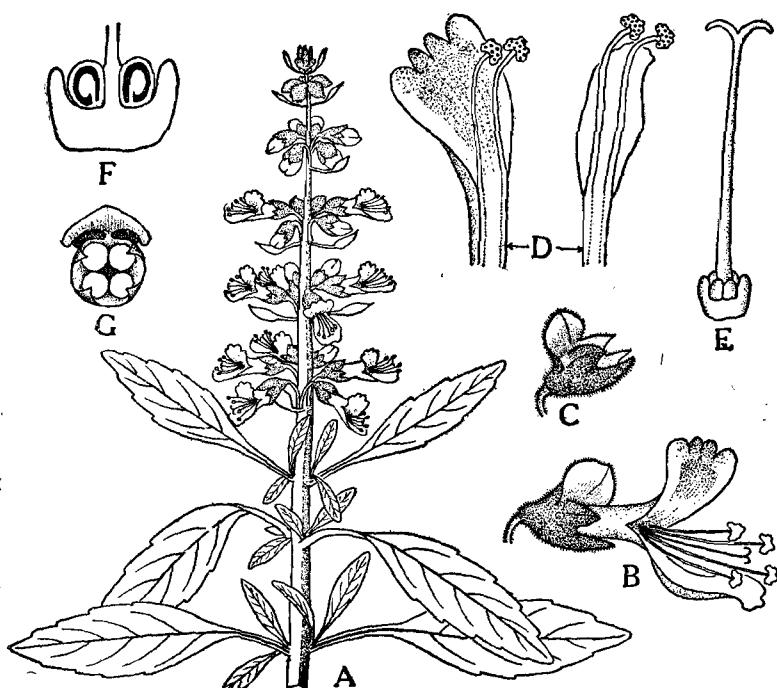

Habit: herbs and undershrubs, with square stem. **Leaves**: simple, opposite or whorled, with oil-glands. **Flowers**: zygomorphic, bilabiate, hypogynous and bisexual. **Inflorescence**: verticillaster (see p. 79), sometimes reduced to true cyme. **Calyx**: sepals (5), gamosepalous, unequally 5-lobed, persistent. **Corolla**: petals (5), gamopetalous, bilabiate, i.e. 2-lipped; aestivation imbricate. **Androecium**: stamens 4, didynamous, sometimes only 2, epipetalous. **Gynoecium**: carpels (2), syn-
carpous; disc prominent; ovary 4-lobed and 4-celled, with

FIG. 471. Floral diagram
of *Labiatae*.

one ovule in each cell; style gynobasic, i.e. develops from the depressed centre of the lobed ovary; stigma bifid. **Fruit**: a group of four nutlets, each with one seed. **Floral formula**— $K_{(5)} C_{(5)} \overline{A_4} G_{(2)}$.

Labiate abounds in volatile, aromatic oils which are used in perfumery and also as stimulants.

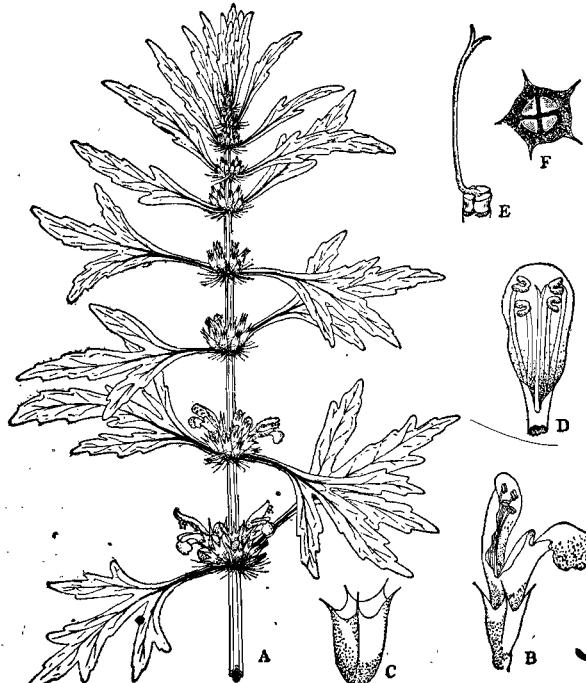

Labiate. FIG. 472A. Basil (*Ocimum basilicum*). A, a branch with inflorescences. B, a flower—bilabiate (note the didynamous stamens); C, calyx; D, corolla split open with epipetalous stamens; E, pistil (note the gynobasic style); F, ovary with the disc in longitudinal section; and G, fruit of four nutlets enclosed in the persistent calyx.

Examples. **Useful plants:** **medicinal**: sacred basil (*Ocimum sanctum*; H. TULSI), mint (*Mentha viridis*; H. PODINA), peppermint (*M. piperita*)—source of peppermint oil and menthol, thyme (*Thymus*)—source of thyme oil and thymol, rosemary (*Rosmarinus*)—yields oil of rosemary, lavender (*Lavandula*)—yields lavender oil, etc.; **ornamental**: sage (*Salvia*; see fig. 202), *Coleus* (see fig. 40), marjoram (*Origanum*)—cultivated for its scented leaves, etc.; **other common plants**: basil (*Ocimum basilicum*), wild basil (*O. canum*), *Leonurus sibiricus*; H. HALKUSHA—fig. 472B), *Leucas linifolia* and *L. aspera* (H. CHOTA-HALKUSHA), etc.

Description of *Leonurus sibiricus* (fig. 472B). An erect annual weed. **Stem**: quadrangular. **Leaves**: simple, opposite-decussate, deeply lobes. **Inflores-**

cence: verticillaster. **Flowers**: bilabiate, bisexual, hypogynous, reddish; bracts subulate. **Calyx**: sepals (5), connate, 5-toothed, unequal, teeth spines-

Labiateae. FIG. 472B. *Leonurus sibiricus*. A, a branch with opposite leaves and inflorescences; B, a flower (bilabiate); C, calyx; D, stamens—didynamous and epipetalous; E, pistil (note the gynobasic style and 4-lobed ovary); and F, fruit of four nutlets enclosed in persistent calyx.

cent, 5-nerved. **Corolla**: petals (5), connate, 2-lipped, upper lip entire and lower lip 3-fid. **Androecium**: stamens 4, didynamous; conniving. **Gynoecium**: carpels (2), syncarpous; ovary 4-lobed; style gynobasic; stigma 2-fid. **Fruit** of 4 dry nutlets.

CHAPTER 3 Selected Families of Monocotyledons

Family 1—Liliaceae (2,600 sp.)

Habit: herbs and climbers, rarely shrubs, with bulb or corm or creeping rootstock. **Leaves**: simple, radical or caudine or both. **Flowers**: regular, bisexual and hypogynous, solitary or in spike, raceme or panicle. **Perianth**: petaloid, usually 6 segments in two whorls, usually free (polyphyllous), sometimes united (gamophyllous). **Androecium**: stamens 6, in two

whorls, rarely 3, hypogynous, free, or united with the perianth (epiphyllous). **Gynoecium**: carpels (3), syncarpous; ovary superior, 3-celled; ovule usually ∞ placentation axile. **Fruit**: a berry or capsule. **Seeds**: albuminous. *Floral formula*—

$P_{3+3}A_{3+3}G_{(3)}$ or $P_{(3+3)}A_{3+3}G_{(3)}$.

Example. **Useful plants**: **vegetables**: onion (*Allium cepa*; fig. 474), garlic (*A. sativum*), leek (*A. tuberosum*), shallot (*A. ascalonicum*), etc.; **medicinal**:

Asparagus racemosus (H. SATWAR), sarsaparilla (*Smilax macrophylla*; H. CHOBCHINI—see fig. 88), Indian aloe (*Aloe vera*; H. GHIKAVAR), etc.; **ornamental**: lily (*Lilium*), glory lily (*Gloriosa superba*; see fig. 115), day lily (*Hemerocallis*), dagger plant or Adam's needle (*Yucca gloriosa*; see fig. 136), *Cordyline*, etc.; **fibre-yielding**: bowstring hemp (*Sanssevieria roxburghiana*; H. MARUL), etc.

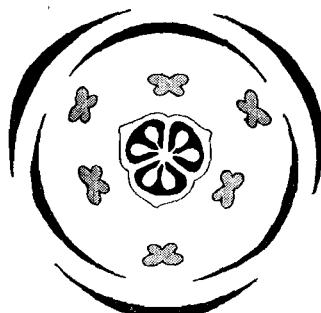

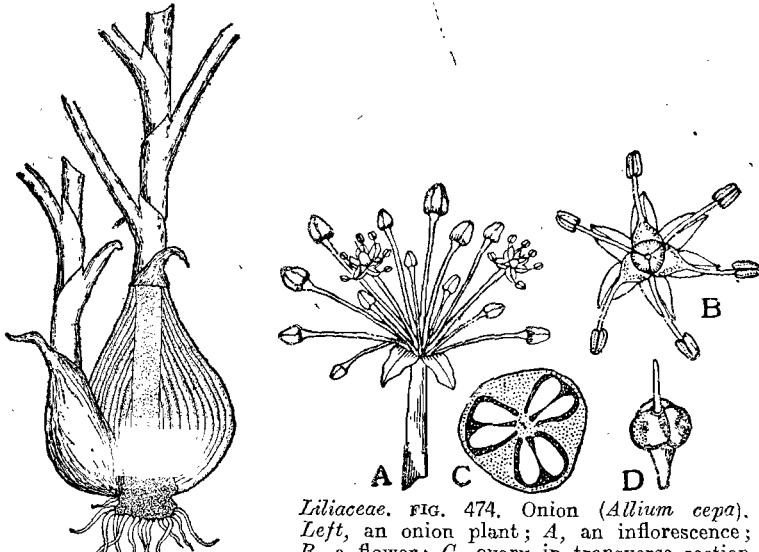

FIG. 473. Floral diagram of Liliaceae.

fig. 136), *Cordyline*, etc.; **fibre-yielding**: bowstring hemp (*Sanssevieria roxburghiana*; H. MARUL), etc.

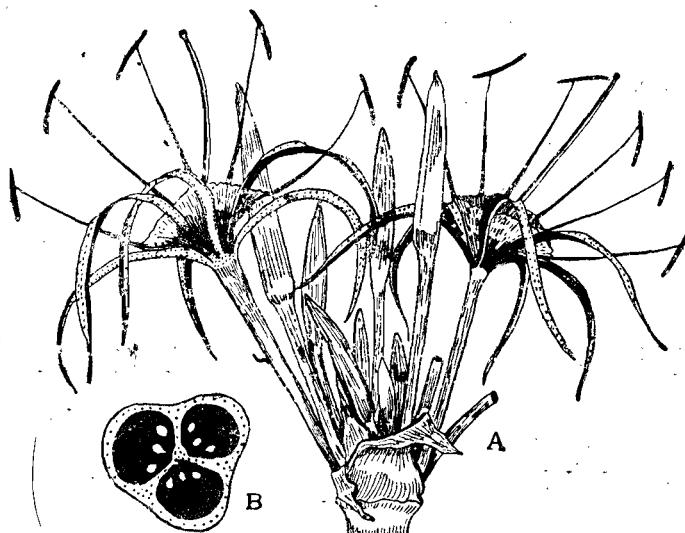

Liliaceae. FIG. 474. Onion (*Allium cepa*). Left, an onion plant; A, an inflorescence; B, a flower; C, ovary in transverse section showing axile placentation; and D, pistil.

Description of Onion Plant (*Allium cepa*; fig. 474). A cultivated herb with tunicated bulb. Bulb surrounded by inner fleshy and outer dry scales. **Leaves**: radical, cylindrical, hollow, sheathing. **Inflorescence**: a terminal umbel on the leafless flowering stem or scape. Bracts 2, sometimes 3, membranous, enclosing the young umbel. **Flowers**: small, white, regular, bisexual, hypogynous, sometimes replaced by bulbils. **Perianth**: of 6 lobes, connate below, campanulate. **Androecium**: stamens 6, free; filaments narrow or dilated at the base. **Gynoecium**: carpels (3), syncarpous; ovary 3-lobed and 3-celled; style short, filiform; stigma minute; ovules usually 2 in each cell. **Fruit** a membranous capsule.

Family 2—Amaryllidaceae (950 sp.)

It has the same general characters as *Liliaceae*, but it differs from the latter in its ovary being inferior.

Examples. Easter lily (*Amaryllis*), pin-cushion lily (*Haemanthus*), spider lily (*Pancratium*; fig. 475), zephyr lily (*Zephyranthes*), eucharis lily (*Eucharis*), *Crinum asiaticum*, *C. latifolium*, American aloe or century plant (*Agave americana*), tuberose (*Polianthes tuberosa*), daffodil (*Narcissus*), etc.

*Amaryllidaceae. FIG. 475. Spider lily (*Pancratium*). A, inflorescence; and B, ovary in transverse section showing axile placentation.*

Family 3—Palmaceae (1,500 sp.)

Habit: shrubs or trees, except cane (*Calamus*) which is a climber. **Stem**: erect, unbranched and woody, rarely branched. **Leaves**: usually forming a crown, plaited in bud, sometimes very large, either palmately cut or divided (**fan palms**) or pinnately cut or divided (**feather palms**); petiole often with sheathing base. **Flowers**: sessile, often produced in immense numbers, regular, hypogynous, unisexual or bisexual, in simple

or compound spadix enclosed in one or more sheathing spathes; either monoecious or dioecious. **Perianth** in two series, 3+3, the outer persistent in the female flower. **Androecium**: stamens usually in two series, 3+3; filaments free or connate; anthers versatile, 2-celled. **Gynoecium**: carpels (3) or 3, syncarpous or apocarpous; ovary superior, 1- or 3-locular, with 1 or 3 ovules. **Fruit**: a drupe or berry. **Seed**: albuminous. **Floral formula**—male flower: $P_{3+3}A_{3+3}G_0$, and female flower: $P_{3+3}A_0G_{(3)} \text{ or } 3$.

Economically it is one of the most important families. Many palms such as the palmyra-palm, toddy-palm, date-palm, coconut-palm, etc., are tapped for toddy (fermented country liquor) or for sweet juice from which jaggery or sugar is made, and they also (except the toddy-palm) yield edible fruit. Coir fibres of coconut-palms are used for making mats, mattresses and brushes, and also for stuffing cushions. Leaves of many palms are woven into mats, hats and baskets and also used for thatching. Some palms yield oil, e.g. coconut-palm, oil-palm, etc. Sago-palms yield sago, which is obtained by crushing the pith. Betel-nut is used for chewing with betel leaf. Cane is used for making chairs, sofas, tables and baskets and also for a variety of other purposes. Many palms are ornamental. **Examples.** **Fan-palms**: palmyra-palm (*Borassus flabellifer*); talipot-palm (*Corypha umbraculifera*) bears a huge inflorescence once only after about 150 years and then dies; oil-palm (*Elaeis guineensis*), *Hyphaene* shows dichotomous branching; double coconut-palm (*Lodoicea seychellarum*), a native of the Seychelles Islands, bears the largest seed and fruit (see fig. 238), etc. **Feather-palms**: Indian sago-palm or toddy-palm (*Caryota urens*), coconut-palm (*Cocos nucifera*), date-palm (*Phoenix sylvestris*), betel-nut-palm (*Areca catechu*), sago-palm (*Metroxylon rumphii*), cane (*Calamus*), etc.

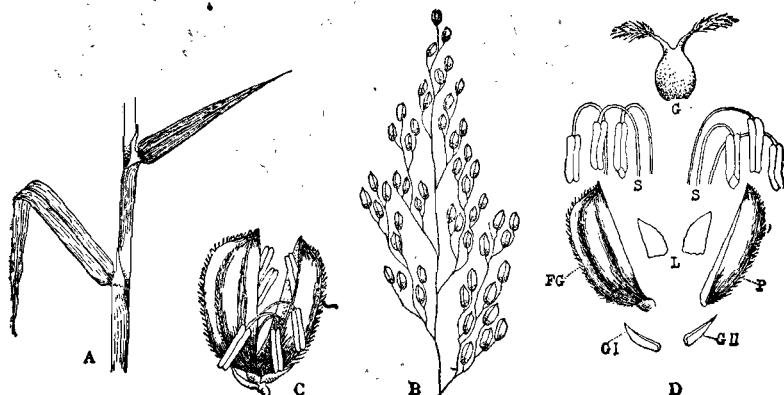

Family 4—Graminaceae

Habit: herbs, rarely woods, as bamboos. **Stem**: cylindrical with distinct nodes and internodes (sometimes hollow). **Leaves**: simple, alternate, distichous, with sheathing leaf-base which is split open on one side opposite to the leaf-blade; a hairy structure called the *ligule* is present at the base of the leaf-blade. **Inflorescence**: usually a spike or panicle of spikelets (see fig. 141); each spikelet consists of one or few flowers, and bears at the base two *empty glumes*, a little higher up a flowering glume called *lemma*, and opposite to the lemma a somewhat smaller glume known as the *palea* (see fig. 476D). The flower remains enclosed by the lemma and the palea. **Flowers**: usually bisexual, sometimes unisexual and monoecious. **Perianth**: represented by two minute scales called the **Iodicules**. **Androecium**: stamens 3, sometimes 6, as in rice and bamboo; anthers versatile and pendulous. **Gynoecium**: carpel 1; ovary superior, 1-celled, with 1 ovule; stigmas 2, feathery. **Fruit**: caryopsis. **Seed**: albuminous **Floral formula** $P_{\text{iodicules}}(2) A_3 \text{ or } 6 G_1$.

From an economic standpoint *Graminaceae* is regarded as

the most important family, as cereals and millets, which constitute the chief food of mankind, belong to this family. Most of the fodder crops which are equally important to domestic animals also belong to this family. The importance of bamboo, thatch grass and reed as building materials, and of sugarcane as a source of sugar and jaggery is well known. The importance of sabai grass and bamboo as a source of paper pulp cannot be over-emphasized.

Examples. Useful plants: cereals such as rice (*Oryza sativa*; fig. 476), wheat (*Triticum sativum*), maize or Indian corn (*Zea mays*; fig. 477), barley (*Hordeum vulgare*), etc., millets such as *Sorghum vulgare* (H. JUAR), *Pennisetum typhoides* (H. BAJRA), *Eleusine coracana* (H. MARUA), etc.; sugarcane (*Saccharum officinarum*), thatch grass (*S. spontaneum*), bamboo (*Bambusa*), reed (*Phragmites*), lemon grass (*Cymbopogon*), saboi grass (*Ischaemum*), etc.; **other common plants:** various grasses such as dog grass (*Cynodon dactylon*; H. DOOB), love thorn (*Chrysopogon aciculatus*), *Imperata*, *Panicum*, etc.

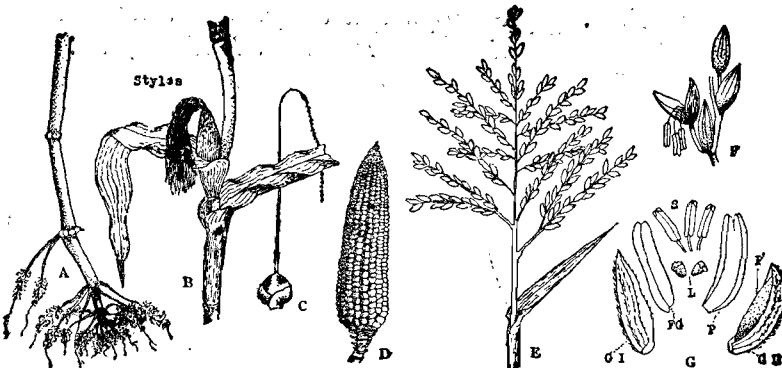

Graminaceae. FIG. 476. Rice (*Oryza sativa*). A, portion of a branch with sheathing leaves and ligules; B, a panicle of spikelets; C, 1-flowered spikelet (note the glumes and stamens); D, spikelet dissected out—G I, first empty glume; G II, second empty glume; FG, flowering glume; P, palea; L, lodicules; S, stamens; and G, gynoecium.

(b) **Description of Maize Plant (*Zea mays*; fig. 477).** This is a tall, stout, annual grass cultivated during the rainy season. The plant is monoecious, bearing male and female spikelets in separate inflorescences. **Roots** are adventitious in nature, developing from the lower nodes; while the **stem** is solid and provided with distinct nodes and internodes. **Leaves** are long, broad and flat, with a distinct sheathing base enclosing the stem; they are simple, alternate and distichous; a ligule is present at the base of the leaf-blade. **Inflorescences** are of two kinds: male

spikelets in a terminal panicle, while female spikelets in axillary spadices borne lower down, each enclosed by a number of spathes.

Male Spikelets occur in pairs—one sessile and the other stalked; each spikelet is 2-flowered. **Glumes** I and II distinctly nerved and empty; glume III (flowering glume) and glume IV (palea), which are hyaline, enclose a flower. **Perianth** is represented by two small fleshy cup-shaped lodicules. **Androecium**: stamens 3; anthers linear and pendulous.

Female Spikelets are densely crowded in several vertical rows on the fleshy rachis and are sessile. Each spikelet with a lower barren (extremely reduced) floret and an upper fertile (normal) one. **Glumes** I and II membranous, broad and empty; glume III (flowering glume) and glume IV (palea) hyaline and enclose a flower. Lodicules absent or very feebly developed. **Gynoecium**: carpel 1; ovary obliquely ovoid and plano-convex; style 1 (really 2 fused into 1), very long and bi-fid at the tip; styles and stigmas papillose and hang out in a tuft from the top of the spadix. **Fruit** or maize grain is a caryopsis. It is albuminous with distinct scutellum (see fig. 26B). Flowers are anemophilous, i.e. pollination is brought about by wind (see fig. 203) and after fertilization the female spadix develops into the maize cob.

Graminaceae. FIG. 477. Maize or Indian corn (*Zea mays*). A, adventitious roots; B, female spadix in the axil of a leaf; C, female spikelet; D, ripe cob; E, a panicle of male spikelets; F, two pairs of male spikelets; and G, a male spikelet dissected out—G I, first empty glume; G II, second empty glume; P', palea of the lower flower; FG, flowering glume; P, palea of the upper flower; L, lodicules; and S, three stamens of the upper flower.

PART VIII EVOLUTION AND GENETICS

CHAPTER I *Organic Evolution*

Evolution means the descent of a new form of plant or animal from the pre-existing one. Biologists have been finally led to believe in the doctrine of evolution by the epoch-making deductions of Charles Darwin in 1859, as opposed to that of creation believed earlier particularly by the theosophists. It is now universally accepted that all higher and more complex forms of life—plants and animals—have evolved from lower and simpler forms. Even the minute organisms like bacteria are not newly formed, as proved by Louis Pasteur, a French scientist and founder of the science of Bacteriology, in the year 1864. Once life came into existence it has become continuous, progressing and changing through successive generations and finally giving rise to the present forms of plants and animals through many millions of years. Evolution is proceeding even now.

Life originated in water (in the sea) and it is generally thought that the first organisms were some forms of aquatic bacteria. They could manufacture organic substances from inorganic materials. The next phase in evolution was possibly the appearance of blue-green algae. Primitive unicellular animals might have originated at this stage, and they formed another line of evolution. Later, with the appearance of green algae which could utilize sunlight as a source of energy the trend of evolution leading to higher plants became established. Life remained confined to water for many millions of years, later it invaded land and became more and more complex.

Evidence of Organic Evolution

1. **Geological Evidence.** The remains of ancient plants and animals preserved in rocks are called **fossils**. Rocks formed in successive layers in different geological ages and periods of the earth have been found to bear fossils of particular types of plants and animals (others being non-existent then). From fossils we thus know about the life of the past, and

therefore, the history of the appearance of new species and the disappearance of old species in successive stages, and their habit and habitat. Thus, based on fossil records it has been possible to trace the gradual changes in the types of plants and animals through the successive periods of the earth. It can be asserted, therefore, that fossils bear sound evidence regarding the trend of evolution from the simpler to the more complex forms. Fossils are, therefore, of special interest and importance in this respect. Fossils, however, show wide gaps in the evolutionary history of plants and animals.

2. Taxonomic Evidence. According to resemblances and differences we classify plants and animals into certain well-marked groups, the members of each group resembling one another more closely. It is difficult to conceive of the similarities in forms without having recourse to evolution. Besides, it is seen that between two or more species of a particular genus there are intermediate forms linking such species (*intergrading species*). If species were constant the occurrence of such forms could not be accounted for.

3. Morphological and Anatomical Evidence. Similarities in morphological and anatomical characters among certain groups of plants, and among certain groups of animals, are very characteristic from the standpoint of evolution. The development of different organs, tissues, advance of sporophyte, reduction of gametophyte, stele, vascular tissue, etc., among plants, and similarly the development of different organs and tissues, nerves, bones, brain, etc., among animals, all in successive stages, show evolutionary tendencies among plants and animals, and lend support to the theory of evolution.

4. Embryological Evidence. The study of the nature and development of the embryo shows a great resemblance among certain groups of plants and of animals. For example, the embryos of dicotyledons (in general) look alike; those of mammals also look alike. Similar is the case with other groups of plants and animals. The striking resemblance in structure and development of the embryos in them can only be explained on the basis of evolution, i.e. descent of forms from a common ancestry. Besides, in all cases one fact at least is common, i.e. the embryo develops from the egg-cell or ovum. Some-

times some organs of plants or animals show a striking resemblance to certain forms from which they have possibly been derived. Thus when a fern spore germinates it resembles a filamentous alga; it then assumes a thalloid form resembling a liverwort; and finally it grows into a fern plant. Seedlings sometimes show their resemblance to plants which may be their ancestors. Thus the seedling of the Australian *Acacia* shows a bipinnate compound leaf like other species of *Acacia*, although the adult Australian *Acacia* has only the winged petiole or rachis (phyllode) without the compound leaf. Likewise the frog passes through a tadpole stage resembling a fish which is supposed to be its ancestor.

5. Evidence from Geographical Distribution. It has been seen that many allied species of plants in their wild state remain confined to a particular area. The explanation is that they sprang up from a common ancestor in that region and could not migrate owing to some barriers such as high mountains, seas and deserts. Thus we find that double coconut-palm (*Lodoicea*) originated in Seychelles, the traveller's tree (*Ravenala*) in Madagascar, *Eucalyptus* in Australia, cacti in the dry regions of tropical America, cactus-like spurge (*Euphorbia*) in the deserts of Africa, etc., often with allied species close together, showing thereby that all the allied species have evolved from the same ancestral species.

Mechanism of Organic Evolution

Variation. Variation is the rule in nature. No two forms, belonging even to the same species, are exactly alike. The differences between them are spoken of as **variations**. Variations are the basis on which evolution works. Variations may take place in different organs of plants and animals and may be continued or discontinued in subsequent generations. According to Darwin, a slow but *continuous variation* from generation to generation is the basis of organic evolution. In this type of variation a continuity or gradation is maintained between the individuals of the species. *Discontinuous variation* or **mutation**, on the other hand, means sudden and sharp variation shown by one or more individuals of a species in any one generation. The individuals show no gradations, as in the previous case. This is De Vries' view. As mutation occurs suddenly and spontaneously there is no knowing when a new form will appear by this process.

Heredity. Heredity means transmission of characteristics and qualities of parent forms to their offspring. This is evident from the fact that a particular species of plant on reproduction gives rise to the same species and to no other. Although no two forms are exactly alike, still offspring bear the closest resemblance to their ancestral forms, and they also resemble one another most closely with, of course, individual differences. Heredity tends to keep the individuals of a species within specific limits, while variation tends to separate them. Variation no doubt is responsible for evolution, while heredity is a check on uncontrolled variation.

Chromosome Mechanism in Heredity. The question arises : What is the physical basis of heredity, or in other words, the mechanism of inheritance of parental characters by the offspring? About the year 1884 it became known, primarily due to the work of Strasburger, that the male gamete of the pollen-tube and the egg-cell of the embryo-sac are directly involved in fertilization and reproduction. About the same year Strasburger and Hertwig revealed the fact that it is through the chromosomes of the two gametes (i.e. reproductive nuclei) that the characters of the parent forms pass to the next generation and so on to the successive generations. The conception of transmission of characters through the media of chromosomes is spoken of as *chromosome mechanism of heredity*. It is obvious that any particular character of the parent (e.g. colour of flower) cannot be found in the chromosome; but it may be safely assumed that something representing that particular character must be present in it. That 'something', obscure though it is, is called the *factor* or *determiner* or *gene* for that particular character. The theory of genes in the chromosomes was first introduced by Morgan in 1926. According to the theory of Morgan and his colleagues the chromosomes are the bearers of hereditary characters, and the genes located in them are responsible for all the characteristics of the parent forms and their transmission to the offspring generation after generation. Genes are ultra-microscopic particles occurring in pairs (one paternal and one maternal) in linear series in the chromosomes. The behaviour of genes in transmission of characters is, however, very complicated. Another important fact to be noted in this connexion is that all gametes always have *haploid* (or n) chromosomes and when they fuse in the process of fertilization the *diploid* (or $2n$) number is restored in the zygote— $n+n=2n$.

Theories of Organic Evolution

Lamarck's Theory : Inheritance of Acquired Characters. A theory to explain the cause of evolution was put forward by the French biologist Lamarck in 1809. His theory resolves itself into three factors, viz. (a) influence of the environment, (b) use and disuse of parts, and (c) inheritance of acquired characters. Lamarck held the view that environment plays

the principal part in the evolution of living organisms. He noted many instances of plants where individuals of the same species grown under different environmental conditions showed marked differences between them. From such observations Lamarck held the view that plants react to external conditions, and that as a result of cumulative effects produced by the changed conditions through successive generations new species make their appearance. In the case of animals the changes are brought about by the use and disuse of parts. The use or exercise of certain parts results in the development of those parts ; while disuse or want of exercise results in the degeneration of the parts. He believed that new characters, however minute, acquired in each generation are preserved and transmitted to the offspring (inheritance of acquired characters). The classic example cited in this connection is that of the giraffe. Lamarck's view was that horse-like ancestors of these animals living in the arid region in the interior of Africa had to feed on the leaves of trees. They had necessarily to stretch their limbs to reach up to the leaves. This use or exercise resulted in the lengthening of the neck and the front legs, and thus a new type of animal made its appearance from a horse-like ancestor. His theory is open to certain objections : one objection is that adaptations due to the influence of the environment are very slight and superficial ; another objection is that the inheritance of acquired characters has not yet been proved. In fact if seeds are taken back to the original habitat even after many years the plants return to their original form.

Lamarck was a self-taught man. He worked hard throughout his life but always remained poor. After his father's death Lamarck joined the French army in the Seven Years' War with the Germans. While at Toulon during the war he developed a taste for the study of flowers. After the war he joined a bank in Paris. Now he seriously took to his favourite study of flowers and soon wrote a *French Flora*. He left the

FIG. 478. Jean Baptiste Lamarck (1744-1829), French biologist and propounder of the first theory of evolution in 1809.

bank in pursuit of his study, and travelled in Holland, Germany and Hungary. On his return to Paris he became known as a famous botanist. He used to write on a variety of science subjects, sometimes erratically, and contributed several articles to the French *Encyclopaedias*, then in preparation. After the French revolution (1789), when science was officially recognized, Lamarck was appointed Professor of Zoology at the Museum of Natural History in 1794 at the age of 50 although he knew almost nothing of the subject. However, he seriously and assiduously took to the classification of the Invertebrates. Soon he became a full-fledged biologist. It was Lamarck who first held the view that a species was not constant but changed under the influence of environment and gave rise to new species. Thus he propounded the first theory of evolution by inheritance of acquired characters in 1809. Between 1816 and 1822 Lamarck wrote his important work *Natural History of Invertebrate Animals* in seven volumes. Owing to heavy strain on his eyes he became quite blind for the last ten years of his life. The last two volumes of his work were written out for him by one of his daughters.

Darwin's Theory : Natural Selection. The next theory to solve the problem of evolution was put forward in 1859 by Charles Darwin and published in his *Origin of Species by Means of Natural Selection*. His theory based on a mass of accurate observations, intensive and extensive studies and prolonged experiments for over 20 years led the whole scientific world to believe in the doctrine of evolution. His theory, called the *theory of natural selection*, is based on three important factors: (a) over-production of offspring and a consequent struggle for existence, (b) variations and their inheritance, and (c) elimination of unfavourable variations (survival of the fittest).

Struggle for Existence. If all the seeds of any particular plant were to germinate and all seedlings to grow up into full-sized plants, a very wide area would soon be covered by them in course of a few years. If other plants (and also animals) were to increase at this rate, a keen competition, called the struggle for existence, would be set up at once among them because supply of food, water and space would fall far short of the demand. A struggle would soon ensue, resulting in the destruction of huge numbers of individuals.

Variations and their Inheritance. It is known to all that no two individuals, even coming out of the same parent stalk, are exactly alike. There are always some variations, however minute they may be, from one individual to another. Some variations are suited to the conditions of the environment, while others are not. According to Darwin these minute

variations are preserved and transmitted to the offspring, although no cause for these variations was assigned by him.

Survival of the Fittest. In the struggle for existence the individuals showing variations in the right direction survive, and these variations are transmitted to the offspring; others with unfavourable variations perish. This is what is called by him 'survival of the fittest'. The survivors gradually and steadily change from one generation to another, and ultimately give rise to new forms. These new forms are better adapted to the surrounding conditions.

Natural Selection. Darwin's observations on the variations of domestic animals and cultivated plants served him as a clue to the elucidation of his theory of natural selection. His explanation of natural selection is this: animals and plants are multiplying at an enormous rate. As we know, no two individuals are exactly alike, the new forms naturally show certain variations. Some variations are favourable or advantageous so far as their adaptation to the conditions of the environment is concerned, and others are not so. Owing to an excessive number crowding together a keen struggle for existence ensues. And in this struggle those that have favourable variations and are, therefore, better fitted naturally, survive; the rest perish. Through this survival of the fittest the species change steadily owing to preservation and transmission of minute variations, and gradually give rise to newer forms. Darwin called this process 'natural selection' from analogy to artificial selection. It is the environment that selects and preserves the better types and destroys the unsuitable forms. Although Darwin receives the fullest credit for bringing about the final acceptance of the doctrine of evolution, his theory is open to certain doubts.

Darwin as a mere boy used to take special delight in collecting birds' eggs, insects and rocks and studying habits of birds. He was rather dull in his academic study at school. He was sent to Cambridge to become a minister of religion before entering a church. But during his three years' stay there he used to mix with the Cambridge naturalists. He became a keen beetle-hunter and captured many new species. Now came a definite turning point in Darwin's whole life. He was entertained as a naturalist on board the Admiralty vessel, *H.M.S. Beagle*, which sailed from the shores of England on a long five-year voyage of survey (1831-36) in the South Atlantic and Pacific oceans. This voyage was of immense value to Darwin and to the whole world. His extensive collections of animals (including tiny sea-animals) and strange plants, corals and fossils, and his observations

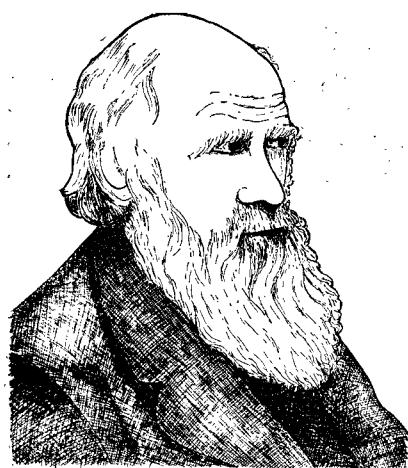

on strange desert plants, rich tropical forests, different kinds of birds, huge tortoises, large lizards, etc., at St Jago Island, Brazil, certain parts of South America, New Zealand and Australia, opened a new avenue

of study for Darwin. The *Beagle* returned to England late in 1836 via the Cape of Good Hope, with Darwin's shipload of specimens. Darwin now settled down to write a long scientific report in five volumes which took him about twenty years to complete. His intensive work for this prolonged period, his keen observations on domestic animals and cultivated plants, his wide study of all connected scientific papers published till then, and his clear thinking finally led him to formulate the theory of evolution. But unfortunately for Darwin, while he was giving final and concrete shape to his ideas of evolution by natural selection

FIG. 479. Charles Darwin (1809-1882), famous English biologist and founder of the theory of evolution in 1859.

he received an essay from a young naturalist, rather an explorer, Alfred Russell Wallace (1823-1913) working independently far away in the Malay Archipelago. Darwin was struck by the ideas expressed in that essay, which tallied almost word for word with his own. Without either claiming priority a joint paper was published on the above subject in 1858 under both their names. Wallace, however, recognized Darwin's superiority as a naturalist and yielded leadership to him. The following year, 1859, Darwin published his epoch-making book *Origin of Species*—the fruit of many years of hard labour and study. The book caused a tremendous stir all over the world. It, however, met with bitter attack from a large section of the people for his daring act against God and religion. But his theory survived, and Darwin came to be recognized as the founder of the theory of evolution.

De Vries' Theory: Mutation. Another theory to explain the cause of evolution was advanced by the Dutch botanist Hugo De Vries in 1901-3. He held that small variations, which Darwin regarded as most important from the standpoint of evolution, are only fluctuations around the specific type. These variations are not inheritable. De Vries held that large variations appearing suddenly and spontaneously in the offspring in one generation are the cause of evolution. These variations De Vries called 'mutations'. He observed an evening primrose (*Oenothera lamarckiana*), introduced from America, grow-

ing in a field in Holland. Among numerous plants he found two types quite distinct from the rest. These new types had not been described before, and having bred true he regarded them as distinct species. *Oenothera lamarckiana* and the new species were removed to his garden at Amsterdam, and cultivated through many generations. It was found that among thousands of seedlings raised a few appeared that were different from the rest. These when raised, generation after generation, always came true to type. These new forms are known as *mutants*. He concluded that his mutation theory explained the cause of evolution. While De Vries agreed with Darwin's view regarding natural selection weeding out unsuitable forms, he held the view that new species are not formed, as Darwin said, by the slow process of continuous variations.

De Vries was educated at Leyden, Heidelberg and Wurzburg. Later he became a professor (1877-1918) at the University of Amsterdam. Once while on a field trip he was struck by the appearance of some new forms growing among a mass of evening primrose (*Oenothera*). This attracted him to the study of botany and evolution. His experimental methods of work, specially on *Oenothera*, led him to the rediscovery in 1900 of Mendel's laws of heredity, and to the elucidation of the theory of evolution by sudden and discontinuous variations which he called mutations. His *mutation theory* (1901-3), as distinct from Darwin's slow and continuous variations by natural selection, explains the cause of evolution, and is regarded as the greatest contribution to the history of evolution. He also went to America to study *Oenothera* in its natural habitat. *Plant Breeding* (1907) is another of his best known works. After his retirement from the University he established an experimental garden at Hiversum and continued his experimental work in producing new forms through many generations of cultures.

FIG. 480. Hugo De Vries (1848-1935), Dutch botanist and founder of the mutation theory of evolution in 1901-3.

CHAPTER 2 *Genetics*

Genetics is the modern experimental study of the laws of inheritance (variation and heredity). The first scientific study on genetics was carried out by Gregor Mendel. He entered a monastery in Brunn, Austria, where he carried on his scientific investigations on hybridization of plants. The results of his eight years' breeding experiments were read before the Natural History Society of Burnn in 1865, and the following year were published in the transactions of that Society. But his work remained unnoticed until 1900, when three distinguished botanists, Hugo De Vries in Holland, Tschermak in Austria and Correns in Germany, discovered its significance. Since then Mendel's work has formed the basis of the study of genetics. Mendel died in 1884 before he could see his work accepted and appreciated.

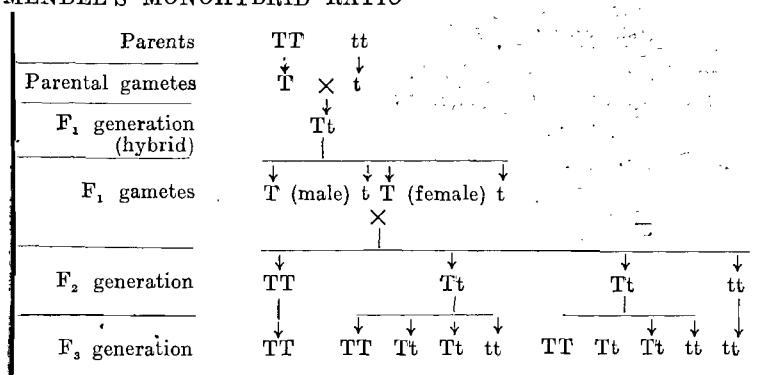

Mendel's Experiments. Mendel selected for his work the common garden pea. In the pea he found a number of contrasting characters—flowers purple, red or white; plants tall or dwarf; and seeds yellow or green, smooth or wrinkled. He concentrated his attention on only one pair of characters at a time, and traced them carefully through many successive generations. In one series of experiments he selected tallness and dwarfness of plants. The results he achieved in these experiments were the same in all cases. It did not matter whether he took the dwarf plant as the male and the tall plant as the female, or vice versa.

Monohybrid Cross. For monohybrid cross only one pair of contrasting characters is taken into consideration at a time. Mendel selected a pea plant, 2 metres in height, and another, 0.5 metres in height. He brought about artificial crossings between the two. The progeny that resulted from these crossings were all tall. This generation, known as the first filial generation or F_1 generation, was inbred. Seeds were collected and sown next year. They gave rise to a mixed generation of talls and dwarfs (but no intermediate) in the ratio of 3 : 1, i.e. three-fourths talls and one-fourth dwarfs. This generation is known as the second filial generation or F_2 generation. All dwarfs in subsequent generations bred true, producing dwarfs only. Seeds were collected separately from each tall plant and sown separately. It was seen that one-

third of the talls bred true to type, while the other two-thirds again split up in the same ratio of 3 : 1. The F_2 ratio is, therefore, 1 : 2 : 1, i.e. *one-fourth* pure talls, *half* mixed talls, and *one-fourth* pure whites.

The above scheme of inheritance may be represented as follows. Here T represents the factor for tallness, and t the factor for dwarfness.

MENDEL'S MONOHYBRID RATIO

Mendel's Laws of Inheritance. From the results of his experiments on carefully selected crossings Mendel formulated certain laws to explain the inheritance of characters, as follows.

1. **Law of Unit Characters.** This means that all characters of the plant are units by themselves, being independent of one another so far as their inheritance is concerned. There are certain factors or determiners (now called *genes*) of unit characters, which control the expression of these characters during the development of the plants.

2. **Law of Dominance.** The characters, as stated above, are controlled by factors or genes. These occur in pairs (arranged in a linear fashion in the chromosome, as now known) and are responsible for tallness and dwarfness separately. One factor may mask the expression of the other. Thus in the F_1 generation all the individuals are tall, the other character remaining suppressed. The character that expresses itself in the F_1 generation is said to be *dominant*, and the character that does not appear in the F_1 generation is said to be *recessive*. The factor for the recessive character is, however, always

present in the F_1 individuals. In the above experiment tallness is the dominant character and the suppressed dwarfness is the recessive character. The contrasting pairs of characters are called **allelomorphs**. Thus tallness and dwarfness are allelomorphs.

3. Law of Segregation. The factors for the contrasting characters remain associated in pairs in the somatic cells of each plant throughout its whole life. Later in its life-history when spores (and subsequently gametes) are formed as a result of reduction division, the factors located in homologous chromosomes become separated out, and each of the four spores (and gametes) will have only one factor (tallness or dwarfness) of the pair but not both, i.e. a gamete becomes *pure* for a particular character. This law is also otherwise called the law of *purity of gametes*.

Mendel also experimented on other pairs of alternative characters, and he found that in every case the characters followed the same scheme of inheritance. Thus in the garden pea he discovered that coloured flower was dominant over white flower; yellow seed over green seed; and smooth seed over wrinkled seed.

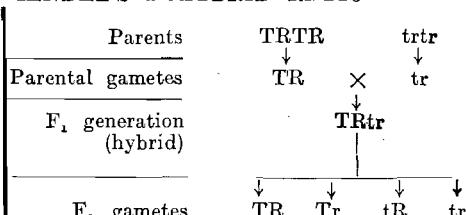

Dihybrid Cross. For the dihybrid cross two pairs of contrasting characters are taken into consideration at a time. Mendel selected a tall plant with red flowers and a dwarf one with white flowers. Four unit characters are, therefore, concerned in the dihybrid ratio. Factors for tallness or dwarfness and red flowers or white are independently inherited, and may be considered to be located in separate chromosome pairs. Artificial crossing was brought about between these two plants. In the F_1 generation all individuals were tall with red flowers; for tallness is dominant over dwarfness, and coloured flowers dominant over white. When the seeds from the F_1 generation were grown, a segregation of characters showing all possible combinations, took place in the following proportions: 9 red talls, 3 white talls, 3 red dwarfs, and 1 white dwarf. This 9: 3: 3: 1 is the dihybrid ratio.

Nos. 1, 2, 3, 4, 5, 7, 9, 10, 13	are tall-red	= 9
Nos. 6, 8, 14.....	tall-white	= 3
Nos. 11, 12, 15.....	dwarf-red	= 3
Nos. 16.....	dwarf-white	= 1

It will further be noticed that Nos. 1, 6, 11 and 16 are *homozygous* (i.e. they have two similar gametes), breeding true; while the rest are *heterozygous* (i.e. they have two dissimilar gametes), segregating in the next generation.

- No. 1 (TRTR) will breed true for tall-red
- No. 6 (TrTr).....tall-white
- No. 11 (tRtR).....dwarf-red
- No. 16 (trtr).....dwarf-white

MENDEL'S DIHYBRID RATIO

(See below for the next generation)

Male gametes of F₁

		TR	Tr	tR	tr	F ₂ generation
		TR	TR	TR	TR	
Female gametes of F ₁	TR	TRTR (tall-red) [1]	TRTr (tall-red) [2]	TRtR (tall-red) [3]	TRtr (tall-red) [4]	
	Tr	TrTR (tall-red) [5]	TrTr (tall-white) [6]	TrtR (tall-red) [7]	Trtr (tall-white) [8]	
	tR	tRTR (tall-red) [9]	tRTr (tall-red) [10]	tRtR (dwarf-red) [11]	tRtr (dwarf-red) [12]	
	tr	trTR (tall-red) [13]	trTr (tall-white) [14]	trtR (dwarf-red) [15]	trtr (dwarf-white) [16]	

Mendel developed a love for gardening, while still a mere boy. He was a good student at school. Soon after his father met with an accident from a falling tree and became invalid, Mendel had to struggle hard for want of money, and finally left school in 1840 at the age of 18. Through the generous help of his sister Mendel took a two-year course in Philosophy, and at the advice of Prof Franz of Brunn Mendel entered the Monastery at Brunn, and lived there, with a short break, for about 41 years till his death in 1884. While at Brunn he took a course in Theology and became a High School teacher. Without much

scientific background he was unsuccessful as a science teacher. Abbe Napp, then in charge of the Monastery, sent Mendel to the

University of Vienna to study science for two years. On completion of the course Mendel returned to the Monastery and joined Brunn High School opened just then (1852) as a science teacher. The Monastery had spacious grounds, and Mendel carried out most of his experiments on heredity there during the period of 1856-1864. He established the laws of heredity for the first time and put genetics (later also called Mendelism in his honour) on a sound scientific basis (read text). In 1864 Mendel became the Abbe of the Monastery. He could hardly then, owing to heavy official duties, pursue his own scientific work. He became rich and was very generous to others. He never forgot his benevolent sister and was fond of his nephews.

Plant Breeding. The subject of plant breeding, although developed in recent

FIG. 481. Gregor Johann Mendel (1822-84), Austrian monk, biologist and famous geneticist. He established the laws of inheritance of characters in 1865-66.

times on modern scientific lines after Mendel's discoveries, was known in early times to the Egyptians and Assyrians. Later during the 18th and 19th centuries several artificial crossings were made by many workers and interesting results obtained in the form of new varieties. But it was Mendel who first laid the foundations of plant breeding on a scientific basis and formulated the laws of inheritance of characters. Plant breeding consists in producing new types of offspring by artificial pollination brought about between the flowers of two different species, varieties or even genera. By this process, also called **crossing** or **hybridization**, it has been possible to combine in the offspring certain desired characters of both the parents. In actual practice the stamens of a flower (bisexual) are removed before its anthers mature, and the flower then with the gynoecium intact covered with a paper or muslin bag to prevent natural pollination. When the stigma of this flower matures, pollen from another selected parent is applied to it. The offspring resulting from such a cross are new types, called **hybrids**, which are often more vigorous than the parent forms. This phenomenon is spoken of as **hybrid vigour** or **heterosis**. The **economic importance** of cross-breeding is manifold and almost unlimited, and already much has been achieved in various agricultural and industrial crops regarding their yield, quality and other useful characters (see pp. 371-2).

PART IX ECONOMIC BOTANY

CHAPTER I *General Description*

Economic Botany deals with the various uses of plants and plant products as applied to the well-being of mankind. It also includes various practical methods that may be adopted for their improvement in one or more directions as needed by man. The economic uses of plants are varied and, therefore, the scope for improvement is immense to meet man's ever-increasing needs. The primary needs of mankind are, of course, **food, clothing** and **shelter**, which originally the gifts of nature, were subsequently improved by man through the application of his scientific knowledge. The gifts of nature are almost unlimited, and thus a variety of useful products are obtained from the plant kingdom.

Methods of Improvement. The methods commonly employed for the improvement of crops in terms of yield, quality, etc., are (1) selection, (2) breeding, (3) improved methods of cultivation, (4) proper use of chemical fertilizers and manures, (5) selection and use of 'quality' seeds, (6) judicious selection of crops for a particular locality, (7) protection against diseases and pests, and (8) proper irrigation by suitable methods.

Selection consists of picking out the best individuals among a field crop in respect of one or more desired economic characters, and collecting the seeds from them for the next sowing. Second and third selections are made in the same way. Finally the promising ones are used for field trials, always keeping the best and rejecting the rest. By this method an advancement of quality and quantity has been achieved in India in a number of crops, e.g. rice, cotton, millets, e.g. *Sorghum* (JUAR or CHOLAM), *Pennisetum* (BAJRA), *Eleusine* (RACI), etc.

Plant Breeding consists in combining into the offspring certain desirable characters met with in two separate parent plants belonging to two different but allied species, or varieties or sometimes even genera (see p. 370). The **economic importance** of this method is immense, and achievements in this direction in various agricultural and industrial crops

regarding their yield, quality and other useful characters have already been considerable. Thus in America new types of wheat, maize, tomato and potato—all high-yielding and disease-resistant—have been evolved by following the practical method of plant breeding. In Russia new varieties of summer and winter wheat (wheat X couch grass, and wheat X *Elymus*), and of barley (barley X *Elymus*) are some of the outstanding achievements. In India also a considerable amount of work has been done in this direction with desired results in many cases. Thus improved strains of rice, wheat, millets, maize, sugarcane, pulses, oil-seeds, cotton, tobacco, jute, flax, hemp, etc., combining higher yield, better quality and resistance to pests and diseases, have been evolved by cross-breeding selected varieties. The results have been spectacular in some cases. Thus several superior strains of rice have been evolved in different rice-growing States. New improved varieties of wheat have been similarly produced. A new wheat, New Pusa 4 (or NP 4), evolved by the Indian Agricultural Research Institute at Pusa (shifted to New Delhi in 1936 after the great Bihar earthquake in 1934) was awarded the first prize many times at International Exhibitions held in America, Australia and Africa. Recently some new strains of wheat have been evolved by this Institute to suit different climatic regions of India. Besides, new millets and maize (see p. 374) have been evolved, which yield 50% more than the common varieties. A recent success of the Institute is the production of a sweet-flavoured tomato with high vitamin content, evolved by crossing a cultivated variety with a wild South American variety. New types of sugarcane evolved at Coimbatore have already become world-famous. They are now widely grown, materially contributing to the growth and expansion of the sugar industry in India. There is still ample scope for improvement of several crops for food and industry.

CHAPTER 2 *Economic Plants*

Economic plants are numerous and have a variety of uses. Many of them occur in nature, particularly in hills and forests, while a good number of them are cultivated for food and industry. From the economic standpoint such plants may be classified under the following heads : (A) food—(i) cereals,

(2) millets, (3) pulses, (4) vegetables, (5) vegetable oils, (6) sugar, (7) fruits and (8) fodder for cattle; (B) timber; (C) fuel; (D) fibres; (E) medicinal plants; (F) beverages; (G) spices; and (H) rubber. It may be noted that India is the largest producer of tea, groundnut and sugarcane.

A. Food. Plants and parts of plants to be used as food must contain sufficiently high percentages of carbohydrates, proteins and fats and oils together with one or more vitamins and essential minerals. Food contributes to the nourishment of the body and enhances the power of resistance to diseases and environmental changes.

i. Cereals. All cereals and millets are rich in starch, and generally contain vitamins A, B and C. They belong to *Graminaceae*, and are cultivated as annual crops. Cereals form the main food of mankind, and in India they occupy about 60% of the total area under cultivation. Even then the supply is far short of the demand, and a huge quantity (3.5 to 4.5 million tonnes) is imported from outside every year. The major cereals are rice, wheat and maize, and major millets are *Sorghum* (JUAR or CHOLAM), *Eleusine* (RAGI) and *Pennisetum* (BAJRA).

(1) **Rice** (*Oryza sativa*) is the major agricultural crop in India occupying about 30% of the total cropped area. It is the staple food of the majority of people in India and South East Asian countries, and 95% of the world's rice is produced in these areas. There are several (may be about 4,000) varieties of rice in India alone. Rice is widely cultivated except in north-west India. The plant thrives under conditions of moderately high temperature, plenty of rainfall or irrigation, and heavy manuring. Although some new varieties of rice —finer, disease-resistant and high-yielding—have been evolved in India by selection and breeding, the average yield of the common varieties is very poor, being more or less 1,450 kg. per hectare per year (of course, much more under the Japanese method of cultivation and also under special conditions) as against 3,117 kg. in Egypt, 3,406 kg. in Japan, 3,472 kg. in Italy and 3,718 kg. in Spain, where fields are heavily manured. There is usually a double or even triple cropping of paddy in India (summer and winter). The latter (AMAN) is far better than the former (AUS) in respect of yield and

quality. The average chemical composition of rice is starch 70-80%, proteins 7% and oils 1.5%. Paddy straw is an important fodder.

(2) **Wheat** (*Triticum sativum*) is the second staple food of people in India. It does, however, form the principal diet in Western countries. There are several varieties of wheat, and these may be broadly classified into *hard* and *soft*. The former varieties are adopted for making *suji* and *atta*, while the latter varieties are used for bread-making. Wheat is cultivated mainly in Uttar Pradesh, Madhya Pradesh, Gujarat and Punjab. Grains are sown in October-December and the crop harvested in March-May. Wheat is a universal crop, i.e. it can be successfully grown in both temperate and tropical countries. The average yield of wheat in India is poor; it is only about 677 kg. per hectare per year, as against 1,396 kg. in Canada, 1,708 kg. in Japan, and 2,468 kg. in Great Britain. Several new varieties of wheat—hardy, disease-resistant, high-yielding, with better milling and bread-making qualities—have been evolved in India (see p. 372). Some of the best wheats are grown in Australia, America and Russia. The average chemical composition is starch 66-70%, proteins 12% and oils 1.5%. Wheat straw is a fodder.

(3) **Maize** (*Zea mays*) is an important cereal food for poorer classes of people. It is cultivated both in the hills and the plains, and it does well both in hot and cold climates. The usual sowing season is April-May, and the harvesting season July-August. Each plant commonly bears one cob, sometimes two. The average yield is very low, being about 986 kg. per hectare per year, going up to 1,570 kg. with good varieties grown under favourable conditions. Maize cobs may be 15-25 cm. in length, and the grains golden yellow, dull yellow, red, white, etc., in colour. There are several varieties and hybrids. Some new hybrids of maize have been evolved in India, which are high-yielding, disease-resistant and nutritious. A hybrid maize (Texas 26) evolved by the Indian Agricultural Research Institute at New Delhi yields over 2,800 kg. per hectare per year. Maize grains are taken as a substitute for other cereal grains in many rural areas. Commonly these are ground into flour called cornflour. Leaves and stems form a good fodder, and the grains a nutritious food for farm animals. The average chemical composition is starch 68-70%, proteins 10% and

oils 3.6-5%. In addition the grains contain an appreciable quantity of calcium and iron.

2. **Millets.** Smaller grained cereals are commonly called millets, and there are various kinds. (1) *Sorghum vulgare* (JUAR or CHOLAM) is the best of all millets. It affords nutritious food, nearly as good as wheat. It is extensively cultivated in South India, and also in Maharashtra and Gujarat. Three croppings a year are generally practised. The average yield per hectare per year is 785-896 kg., often double this quantity in black soil properly irrigated. The average chemical composition is starch 72%, proteins 9% and oils 2%. *Sorghum* is a good fodder crop. (2) *Eleusine coracana* (RAGI) is an important food crop of Mysore State, and is extensively cultivated in Mysore and Madras. Three croppings are generally practised. The average yield per hectare per year is 785-1,120 kg., sometimes going up to 2,200 kg. in red soil properly irrigated. Average chemical composition is starch 73%, proteins 7% and oils 1.5%. The straw is nutritious fodder for cattle. (3) *Pennisetum typhoides* (BAJRA) is another important millet. It is cultivated almost throughout India. The average yield per hectare per year is 560-670 kg. or a little more. Average chemical composition is starch 71%, proteins 10% and oils 3%. It is not commonly used as a fodder.

3. **Pulses.** As food grains pulses stand next to cereals. They are widely cultivated in India as winter crops in rotation with cereals, occupying about 18% of the total area under cultivation. They belong to *Papilionaceae*. They are valued as food because of their high protein contents averaging 22-25% (in soybean 42-47%); starch content is about 58% and oil content 2%; in gram the oil content may be as high as 5%. They contain vitamins A, B and C (particularly when sprouted). Pulses commonly used in India are gram (*Cicer arietinum*), black gram (*Phaseolus mungo*), green gram (*P. aureus*), pigeon pea (*Cajanus cajan*), and lentil (*Lens culinaris*). Pulses are widely used in various culinary preparations, particularly DAL. The plants form good fodder (with the exception of gram), and having root-nodules for nitrogen fixation (see p. 211), they form excellent green manure. In habit the pigeon pea plant is a shrub; the rest are annual herbs.

4. **Vegetables.** (a) Leafy vegetables like cabbage, lettuce,

spinach, etc., are rich in vitamins, usually A, B, C and E, and should be included in the daily diet. (b) Tuber crops are fleshy underground roots or stems laden with a heavy deposit of food material. Some of the common tuber crops are as follows.

(1) **Potato** is the underground stem-tuber of *Solanum tuberosum*, a herbaceous plant. It is a native of South America, and was first introduced into India by the Portuguese in the early part of the 17th century. The potato holds a unique position among the cultivated crops in many respects. It may be grown in the hills as well as in the plains, and during summer and the cold months. It is a universal article of diet all over the world, and is used in a large variety of culinary preparations. Its yield is very much higher than other cultivated food crops (except tapioca which is mainly confined to Kerala), being about 7-8 tonnes per hectare per year, often much higher under favourable conditions. It is extensively cultivated all over India, both in the hills and in the plains but the yield is low compared to that of other countries. Sandy loam is the best soil for cultivation of potato. Water-logging is very injurious, while irrigation with proper drainage is very necessary. Potato requires about three months to mature, and when the leaves have completely withered it is ready to be lifted. Generally the yield is tenfold of the potato sown. The several varieties may be broadly classified into two—waxy and mealy. Average chemical composition is starch 18-20%, proteins 2% and oils 0.1%. Potato is a good source of starch which has a variety of uses. (2) **Sweet potato** is the underground tuberous root of *Batatas edulis*. There are two common varieties—one with white skin and the other with red skin. Sweet potato is tasty and nutritious, and may be taken raw, boiled or fried, or commonly in curries. The average chemical composition is starch and sugar 29%, proteins 2% and oils 0.7%. (3) **Tapioca** is the large fleshy root of *Manihot utilissima*, a perennial shrub, mainly cultivated in Kerala. The two varieties of tapioca—bitter and sweet—contain some amount of hydrocyanic acid which, however, disappears on boiling or roasting. Tapioca makes tasty curries and is nutritious. Tapioca flour is used in making CHAPATIS, HALWA, pudding and biscuits. Granulated tapioca is sold in the market as a substitute for sago. Tapioca is a good anti-famine food. The plant is propagated by stem-cuttings. The yield may be over 11 tonnes

per hectare per year. (4) **Yam** is the large underground tuber of different species of *Dioscorea*, particularly *D. alata*. Good varieties, when cooked, are palatable and nutritious.

5. **Vegetable Oils.** There are several species of plants yielding oils, edible and industrial, in high percentages. In oil-seeds India holds a prominent position in the world market with her huge export. Oil-yielding plants occupy about 8% of the total cropped area in India. Some of the edible oils used in India are as follows. The oil-cakes are used as valuable fertilizers and as nutritive food for cattle. (1) **Gingelly oil** is obtained from the seeds of *Sesamum indicum*, mostly grown in Uttar Pradesh and Madras, and to some extent only in other States. The seeds yield 45-50% of edible oil used for cooking. Lighting, soap-making, toilet-oil, etc., are its other uses. The average yield of seeds per hectare per year is 450-560 kg. (2) **Coconut oil** is obtained from the dry kernel (copra) of the seed of *Cocos nucifera*, the yield of oil being about 50%. It is a valuable oil used for cooking, lighting, soap-making, and several toilet preparations. Coconut trees grow luxuriantly along sea-coasts, and a healthy tree bears 60-80 (sometimes even 100) coconuts a year, fruiting all the year round. (3) **Groundnut oil** is obtained from the seeds of *Arachis hypogaea* (see fig. 353), the yield of oil being about 43-46%. Groundnut cultivation is now a major agricultural operation in India and occupies the largest area in the world. Madras, Andhra, Gujarat and Maharashtra are the principal areas of its cultivation. The average yield per hectare per year is 900-1,100 kg., or more with good varieties. The oil is extensively used for cooking and also for soap-making. It is the principal commercial oil of the Vanaspati industry. In Europe 'margarine'—an imitation butter—is manufactured from this oil. There is a big export of groundnuts, oil and oil-cake to France, England and Germany. (4) **Mustard oil** obtained from the seeds of *Brassica campestris* and other species is another important vegetable oil widely used in north-eastern India for cooking and anointing the body. Mustard is grown practically all over northern India. The maximum quantity is produced in Uttar Pradesh and Rajasthan.

6. **Sugars.** Of the different kinds of sugars obtained from plants it is cane-sugar (sucrose) that is universally used as a commercial sugar for sweetening various food preparations.

Cane-sugar is obtained from the juicy pith of sugarcane (*Saccharum officinarum*), the yield being usually 10-15% (18-20% in rich varieties) with an average of 13%. 9.5 tonnes of sugarcane yield about 1 tonne of sugar. There are several varieties of sugarcane. Some improved varieties of sugarcane evolved at Coimbatore by breeding are now being widely cultivated in India to feed her numerous sugar mills. Nearly 55% of the sugarcane is used for making CUR (jaggery) and KHANDSARI as products of cottage industry, while approximately 25% goes to the sugar mills for manufacture into white sugar. A small percentage is used for chewing. Sugarcane is grown on a commercial scale in Uttar Pradesh and Bihar and also in Punjab, Madras and Maharashtra. India is the largest cane-growing country in the world but her yield is the poorest, being only about 35-37 tonnes per hectare per year, which is about one-fourth of the yield in other cane-producing countries. The plant is propagated by stem-cuttings. There are about 179 sugar mills in India, mostly located in Uttar Pradesh and Bihar. The total annual production of sugar in India is now about 3 million tonnes. Beet-root is the source of cane-sugar (sucrose) in some cold countries. The root contains 10-20% of sugar, with an average of 13-14%. The plant is cultivated in Europe, Russia and America for the purpose of sugar manufacture. Russia is the biggest producer of sugar-beet.

7. **Fruit.** India abounds in excellent fruits. Apart from their food value they are rich sources of vitamins. Many of them are available out of season in the form of various preserves, either as slices or as jam, jelly, pickle, marmalade, CHUTNEY (sweet or sour), etc. Of the many edible, nutritious and palatable fruits the following may be specially mentioned. (1) **Mango** is the fruit (drupe) of *Mangifera indica*, and its edible part is the mesocarp. It is a mid-summer fruit having over 1,000 varieties. The superior ones range in weight from 200 to 600 gm. or sometimes even more. Mango, regarded as the best of all Indian fruits is often called the 'king of fruits'. It is notable for its very agreeable taste and flavour; besides, it is appetizing, digestive and nutritious; it contains vitamins A, C and a little B. There are over 500 famous varieties of mango in India. Some of them are LANGRA, GULABKHAS and SEPIA of Bihar; LANGRA and DASHERI of Uttar Pradesh; ALFONSO and PAIRI of Maharashtra; KESAR

of Gujarat ; FERNANDIX of Goa ; SIROLI of Punjab ; BANGALORA (or TOTAPURI), SUBARNAREKHA, BANGANPALLE and JEHANGIR of South India ; and MALDA, FAZLI, HIMSAGAR, KOHINOOR, MOHAN-BHOG, GOPALBHOG (possibly the best variety) and KISHEN-BHOG of West Bengal. Uttar Pradesh is the biggest mango-producing State in India, while Bihar ranks second. The mango plant is propagated by grafting (see fig. 368). (2) **Pineapple** is the fruit (sorosis) of *Ananas sativus*. It is extensively cultivated both in the hills and in the plains. Common good varieties of pineapple weigh 1-2 kg. ; specially large varieties may weigh up to 6 kg. or even more. It is propagated by suckers and crowns (see fig. 365). The fruit is fleshy, juicy, sweet, tasty and with an agreeable flavour. (3) **Banana** is the fruit (berry) of *Musa paradisiaca*. There are several edible varieties, each having its own characteristic flavour. The banana is palatable, nutritious and easily digestible. Assam, West Bengal, Kerala and Madras produce some excellent varieties of banana. The plant is propagated by suckers. Ripe fruit contains about 20% of sugar (but no starch) and about 4.7% of proteins. It contains vitamins A, B, C and also D and E. Further it is a source of K, P, Ca and Fe. (4) **Papaw** is the fruit (berry) of *Carica papaya*. Some good varieties may bear fruit weighing up to 3-4 kg., particularly when some of the young green ones are removed. The green fruits are used as a vegetable, while ripe ones are excellent dessert fruits—palatable, refreshing, easily digestible and laxative. The latex contains a digestive enzyme called *papain*. Ripe fruits contain vitamins A and C. Each plant may bear 40-60 fruits. The plant is propagated by seeds. (5) **Orange** is the fruit (hesperidium) of *Citrus reticulata* and a few other species. It is a winter fruit, very juicy and tasty. The plant is a large, much branched shrub, often bearing 300-400 fruits, sometimes more. The keeping quality of the fruit is very poor, and a good quantity sheds and is wasted. Assam, West Bengal, Madhya Pradesh, Delhi, Punjab, Madras, Coorg and Hyderabad are centres of orange cultivation in India. Orange juice contains vitamin C. There are several varieties. Common ones are Mandarin orange (*Citrus reticulata*)—loose-skinned commercial orange, sweet orange (*C. sinensis*)—tight-skinned (Malta, Mosambi or Mosambique and Valentia are varieties of it), sour or bitter orange (*C. aurantium*)—used for making marmalade.

8. Fodder. Fodder is the food for cattle. The importance of feeding the cattle on nutritious fodder to ensure best service from them cannot be over-emphasized. The common fodder of India consists of (a) several green wild grasses and other green plants growing on pasture lands; (b) several grasses cultivated for the purpose, e.g. guinea grass, buffalo grass, *Sorghum* (JUAR or CHOLAM), *Eleusine* (RAGI), etc., (c) many straws, e.g. rice straw, wheat straw, *Sorghum* straw, etc.; (d) hay—grasses and straws cut and dried; (e) many leguminous plants, e.g. lucerne or alfalfa, cow-pea, several pulses including soybean; and (f) soft green leaves of many shrubs and trees. Besides, several oil-cakes left after the extraction of oil from the seeds, e.g. groundnut, cotton, gingelly, coconut, mustard, etc., form nutritive fattening food for cattle.

B. Timber. Timber is the wood (heart-wood) used for various building purposes: houses, boats, bridges, ships, etc., for making furniture, packing boxes, tea-chests, matchsticks and boxes, plywood, etc., and for railway sleepers. Timber and fire-wood (fuel) together with many other important forest products constitute the forest wealth of a country. To be self-sufficient in them a country should normally have about one-third of the total land area under forest. In this respect India lags behind, having only 22.2%. In India Madhya Pradesh has now the largest forest area, while Assam occupies second place. The useful timber trees of Indian forests number over 75 species. The quality of timber depends on its hardness, strength, weight, presence of natural preservatives such as tannin, resin, etc., durability against heat, moisture, and insect attack, workability, grains, colour, porosity, and capacity for taking polish and varnish.

(1) **Teak** (*Tectona grandis*) is the famous timber tree of the Deccan plateau, and also of Madras, Kerala, Maharashtra, Bihar, Orissa and Assam. Teak yields a very valuable timber with straight grains and light golden brown colour. The wood is hard, strong, light to moderately heavy and extremely durable, being immune to insect and fungal attacks. It does not warp, shrink or expand. The timber is largely used for making handsome furniture of various designs. It is also extensively used for doors, windows, beams, rafters, etc. Teak is a very costly wood. While Burma teak is the best, the Deccan plateau produces the best Indian teak. (2) **Indian redwood** or

SHISHAM (*Dalbergia sissoo*) is a tree of the sub-Himalayan forests extending from Assam to Punjab. It yields a valuable timber with fine to medium grains and golden-brown to dark-brown colour. It is hard (harder than teak), strong, very durable and moderately heavy. It makes handsome furniture for which it is largely used. It is easy to work and takes good polish, and is least susceptible to white ants and borers. The timber is also used for posts, rafters and boards. It makes durable carts, coaches and boats. The wood is also widely used for carving. (3) **NEEM** (*Azadirachta indica*) is found all over India, often planted as a roadside tree or in villages; it is also commonly self-sown. The wood is moderately good, dull-red in colour, hard, durable and moderately heavy. It is commercially not an important timber but in villages it is used as posts, beams and rafters in house-building; it is also used in making ploughs, carts and cart-wheels. It has only a limited use as timber. The wood is also used for carving.

There is also a good number of other very valuable timbers such as **SAL**, mahogany, **JARUL**, **GARJAN** or wood-oil tree, rose-wood, toon, chaplash, etc. In the hills common timber trees are pine, fir, deodar, cypress, etc.

C. Fuel. A good fuel is that which produces sufficient heat, burns slowly and is not smoky. The total consumption of fuel required for domestic purposes and for boilers of small engines is enormous. Our forests can maintain a steady supply but transport difficulties often stand in the way. There is a good number of trees yielding fuel, e.g. **BABUL** (*Acacia arabica* and other species), **JHAU** (*Casuarina*), tamarind, *Cassia siamea*, **CHAMPAK** (*Michelia*) and many species of *Albizzia*. The rejected sap-wood chips of **SAL**, **SHISHAM** and some other timber trees make excellent fuel. Bamboo is also extensively used as a fuel.

D. Fibres. Commercial vegetable fibres may be classified as (a) floss fibres or lint, e.g. cotton and silk cotton; (b) bast fibres, e.g. jute, hemp and ramie; (c) coir fibres, e.g. coconut fibres, and (d) leaf fibres, e.g. bowstring hemp and American aloe (*Agave*). (1) **Cotton** is the most important textile fibre of commerce. The fibres are spun into yarn and woven into various kinds of garments, screens, sheets, canopies, sails and a variety of other things. The qualities of cotton fibres are length, strength, fineness, silkiness, etc. Indian cottons are in these

respects poor in quality, having short staples (12.7 to 25.4 mm.), while Egyptian cottons have staple lengths of 31.7 to 38 mm. and American cottons 38 to 50.8 mm. The cultivation of foreign cottons in Indian soil has not proved to be a success yet. Of all the Indian cottons the Broach cotton of Gujarat is the finest. Although the area under cotton in India is the largest in the world her total output is much less than that of other cotton-producing countries. The average annual yield of cotton lint in India is only about 97 kg. per hectare ; while in the U.S.A. it is 177 kg., in Japan 203 kg., in U.S.S.R. over 272 kg., and in Egypt about 416 kg. Maharashtra, Gujarat, Madhya Pradesh, Madras, Mysore, Andhra, Uttar Pradesh, Punjab and Rajasthan are the important cotton-growing areas in India. Black soil is most suitable for cotton cultivation. (2) **Jute** is the bast fibre of *Corchorus capsularis* and *C. olitorius*. Jute is widely cultivated in the low-lying areas of Assam, West Bengal and Tripura, and to some extent only in Bihar, Orissa and U.P. It is essentially a rainy season crop thriving under conditions of flooding at a later stage. Fibres mature with the formation of the fruits. After harvesting, the jute plants are retted in water for about 10 to 15 days, sometimes more. The fibres are then stripped off the stalks by hand. They are then washed, dried in the sun and finally baled. The annual yield usually varies from 823 to 1,646 kg. per hectare. With the extension of cultivation the annual jute production in India has gone well over 5.8 million bales. Jute fibres are extensively used for making gunny bags, cheap rugs, carpets, cordage, hessian (coarse cloth), etc. (3) **Coir** is the husk fibre of dry coconut fruits. The fibres are largely used for making mats, mattings, mattresses, etc., of exquisitely beautiful design and size, and also for making ropes, cords and coarse brushes. They are also used for stuffing sofas and carriage seats. Kerala leads in the production of coconuts and in the manufacture of coir goods in India.

E. Medicinal plants. Our forests abound in medicinal herbs, shrubs and trees. It is estimated that they number over 4,000 species. Of them about 2,500 to 3,000 species are in general use in some form or other. The Eastern Himalayas and the Nilgiri Hills are known to be the natural abodes of many such plants. A good number of them are now being cultivated in different States on experimental and commercial bases. The

Central Drug Research Institute at Lucknow is carrying on research on indigenous medicinal plants. (1) **Quinine**, an alkaloid, is extracted from the thick bark (stem or root) of several species of *Cinchona*, the yield being 2-5%. *Cinchona* is a South American plant introduced into India from Peru by Markham about the year 1858. *Cinchona* is cultivated in the Darjeeling district and in the Nilgiri Hills. Quinine is the most effective remedy for malaria, the disease being responsible for an annual death toll of about 3,00,000 in India. The total production of quinine in India falls far short of her demand. (2) **Sandalwood** is the monopoly of Mysore and Kerala. The heart-wood yields 5 to 7% of a yellow aromatic volatile oil—the sandalwood oil. The oil has many medicinal properties: it is cooling, astringent and useful in biliousness, vomiting, fever, thirst and heat of the body. The seed-oil is used in skin diseases. (3) **Garlic** is a strong-smelling, whitish bulb, the smell being due to a volatile oil contained in it. In addition to its use as a condiment it has certain medicinal properties. It is an effective remedy for rheumatic and muscular pain, and for giddiness and sore eyes. It heals intestinal and stomach ulcers. It is digestive and relieves flatulence and pain in the bowels. It is highly efficacious in torpid liver and dyspepsia. (4) **Penicillin** is the secretory product of a soil fungus called green mould (*Penicillium notatum*). It is a wonder drug of modern times. It is most effective in a variety of infectious diseases (see p. 302).

F. Beverages. They are agreeable liquors meant for drinking. Tea, coffee and cocoa are common such beverages.

(1) **Tea** is now a universal drink. From the tea garden to the tea cup there is, however, a long history. There are different grades of tea. The terminal bud with two leaves forms *fine* tea; the same with three leaves forms *medium* tea; and the same with four leaves forms *coarse* tea. The average yield of manufactured tea varies usually from 450 to 1,120 kg. per hectare per year, and 1.8 kg. of green leaves usually make 0.45 kg. of cured tea. The yield of green leaves per plant is more or less 0.9 kg. India is the largest producer of tea in the world. India produces nearly half of world's total output. Roughly half of India's total output is produced in Upper Assam. There are about 780 tea gardens in Assam (mostly in Upper Assam) and about 240 in North Bengal. Tea is also grown in Kerala,

Madras and Mysore. Tea accounts for 25% of India's total export. The internal consumption of tea has now gone well over 140 million kg. Tea grows in the plains and in the hills up to an altitude of 1,800 metres or even higher, and flourishes in areas with abundant rainfall. Darjeeling tea is noted for its very agreeable flavour, and sells at high rates in both foreign and inland markets. Annual pruning even from the second year is a very important practice helping the plant to 'flush' profusely. Tea bushes require proper irrigation and adequate manuring for increased yield; chemical fertilizers such as sulphate of ammonia are very beneficial to them. Manufactured tea contains 4-5% of tannins (catechins), which are responsible for colour and strength of the infusion, 3.5-5% of caffeine, which is a stimulant for the heart, and a little volatile oil to which the aroma of the tea is due.

Manufacturing Process. After *plucking*, the leaves are spread on bamboo racks for about 18 hours for *withering*, i.e. softening the leaves. The withered leaves are then passed through the rolling machine for half an hour. *Rolling* gives a twist to the leaves and also major chemical changes take place here. *Sifting* is the next operation separating the finer meal which is then removed to the fermentation room for 3 to 4 hours. During *fermentation* the flavour and colour develop. The next is *firing* at a temperature of 93°C. and then to 82°C. until the moisture content is reduced to 3-4%. The manufactured tea leaves are then *sorted*, *graded* and finally *packed* into plywood chests for marketing.

(2) **Coffee** is a favourite drink in South India. Seeds of *Coffea arabica* and *C. robusta*, particularly the former, are the sources of coffee. The aroma of the coffee powder develops on proper and skilful roasting. Certain chemicals are also added for this purpose. A coffee bush usually yields 0.45-0.9 kg. of cured coffee. Coffee contains several vitamins and also caffeine (an alkaloid). The main coffee plantations are in the low hills of South India—Mysore, Madras and Kerala. Coffee is also cultivated in Orissa.

(3) **Cocoa** prepared from the seeds of *Theobroma cacao*, a small tree. Each tree commonly bears 70-80 fruits, each measuring 15-22 × 7-10 cm. Each fruit contains numerous seeds. The fruits are cut or broken open, and the seeds dried, roasted and powdered. Cocoa powder makes a refreshing and nourish-

ing drink. With the addition of certain ingredients chocolate is made out of this powder. On an average 50 pods, each having about 30 good seeds, yield over 1 kg. of cured cocoa. Cocoa-butter is used in medicine. Cocoa is extensively cultivated in tropical America, the West Indies, Brazil, Ghana and Kenya. It is also cultivated in Java and Ceylon. The world's supply comes mainly from Brazil, Kenya and Ghana (Ghana supplying the largest quantity).

G. Spices. Spices are certain aromatic and pungent products used for seasoning and flavouring food and various fruit and vegetable preserves. They are extensively used in cookery and confectionary, hot or sweet CHUTNEY, beverages, etc., or chewing by themselves or with betel leaf. They are also used in medicines. Some of the common spices are as follows. (1) **Cardamom** is the seed of *Elettaria cardamomum*, a perennial herb, cultivated in the Western Ghats, Mysore and the Cardamom Hills of Travancore. The fruit has a yellowish skin, and the seeds contain an aromatic volatile oil (usually 4-6%). The seeds form an important spice. The greater cardamom, whose fruit has a dark-brown skin and is larger in size, comes to the market from Darjeeling and Nepal. They are the products of *Amomum subulatum*, a perennial herb. (2) **Pepper** is the dried berry of the pepper vine (*Piper nigrum*), a rootlet climber. The dried berry forms the black pepper of commerce. Kerala is the principal centre for the cultivation of pepper. It is also grown in Mysore, Madras, Maharashtra, West Bengal and Assam. It is propagated by stem-cuttings. Each pepper vine yields more or less 1 kg. of cured pepper. (3) **Ginger** is the rhizome of *Zingiber officinale*, a perennial herb. It is extensively used in curries, CHUTNEY, pickles and various fruit and vegetable preserves. It enhances taste and flavour, and is digestive. It is cultivated in nearly all States of India but Kerala is a big source of supply. (4) **Cloves** are the dried flower-buds of *Syzygium aromaticum*; the green colour of the buds changes to dark-brown on drying. Cloves are used extensively in curries, preserves and medicines. Clove-oil is extracted from leaves and unripe fruits. Cloves are grown in the Western Ghats and in Kerala but the total output is far short of the demand. The main source of supply is the island of Zanzibar, popularly called the 'Island of Cloves'.

H. Rubber. This is obtained from the latex of *Hevea brasiliensis*, a big tree. The latex is collected by tapping the bark. It is then allowed to coagulate with the addition of water and a little acetic acid. The coagulated mass (rubber) is then separated from the liquid portion, washed and dried in a smoke-house. It is then passed through rollers and pressed into blocks, sheets, crepe, etc. The use of rubber for tyres and tubes of various kinds of vehicles, crepe soles, rubber shoes and garments, rubber sheets, tubings, beltings, and various other goods is well known. Indian rubber is mostly consumed internally within the country. The majority of rubber plantations are in Travancore ; the rest are in Cochin, Malabar and Coorg. The average yield of rubber in India is rather low, being only 336 kg. per hectare. It may be noted that synthetic rubber is gradually coming into use.

APPENDIX I *Questions*

INTRODUCTION

1. What is protoplasm? Give an account of its physical and chemical nature.
2. Enumerate the important differences between the living and the non-living.
3. What are the main characteristics of plants by which they can be distinguished from animals?
4. Classify plants into their main groups. Give the main characteristics of each group. Illustrate your answer with sketches and examples.

PART I. MORPHOLOGY

Chapters 1-2.

1. Classify plants according to their habit, and give a detailed account of various modes of climbing.
2. What are autotrophic and heterotrophic plants? Describe the types of heterotrophic plants that you have studied.
3. Draw a labelled sketch showing the parts of a 'flowering' plant, and briefly mention the functions of these parts.

Chapter 3.

1. Describe the parts of an exalbuminous seed, and the mode of its germination. Give necessary sketches.
2. Describe with the aid of sketches the parts of castor seed or maize grain, and the mode of its germination.
3. What do you understand by epigeal germination? Describe the process with reference to a typical seed.
4. What are the essential conditions necessary for the germination of a seed? Devise an experiment to prove them.
5. Write short notes on endosperm, scutellum, coleoptile, epicotyl and vivipary.

Chapter 4.

1. What are the characteristics of the root by which it can be distinguished from the stem?
2. Give an account of the modified forms of roots. Describe them with sketches and examples.
3. What are adventitious roots? Describe with sketches and examples at least five types of such roots.
4. What are the normal functions of the root? Point out how this organ adapts itself to meet certain specialized functions.
5. Write short notes on endogenous, fusiform root, haustoria, epiphytic root, root-hair and fasciculated roots.

Chapter 5.

1. Describe a vegetative bud as seen in a longi-section. Of what use is it to the plant? Describe the various types.
2. Name and describe the various kinds of underground stems. Why are they not regarded as roots? What are their functions?
3. Describe a potato tuber, and give reasons in support of its morphological nature. How do you distinguish between a stem-tuber and a root-tuber?
4. Describe, with sketches and examples, the various modifications of stems for vegetative propagation.
5. Write short notes on decumbent, caudex, rhizome, bulb, bulbil, tendril, thorn, phylloclade and cladode.

Chapters 6-7.

1. Describe the parts of a typical leaf, and give an account of the various modifications it undergoes.
2. What is venation? Give the principal types. Mention the functions of the system of veins.
3. Distinguish between a simple leaf and a compound leaf, a compound leaf and a short branch. What are the main types of compound leaves?
4. Give a short account of phyllotaxy, and explain what is meant by orthostichy and genetic spiral.
5. What are the normal functions of the

leaf? For what other purposes may it be utilized? 6. How do plants protect themselves against injury by animals? 7. Note any points of morphological interest connected with the following plants: pea, *Smilax*, glory lily, *Polygonum*, rose, *Naravelia*, pitcher plant, *Cardenthera*, Australian *Acacia*, nettle, *Hemiphragma* and snake plant.

Chapters 8-9. 1. What is an inflorescence? Describe the simple raceme types. Give sketches and examples. 2. What kind of inflorescence do you find in gold mohur, aroid, banana, sunflower, coriander, *Ocimum* and grass? Describe any four of them with sketches. 3. Describe the parts of a typical flower, and indicate the functions of these parts. 4. Describe, with sketches and examples, the structure of hypogynous, perigynous and epigynous flowers. Describe the thalamus of *Gynandropsis* and passion-flower. 5. Discuss: 'A flower is a modified shoot'. 6. Explain and cite instances of adhesion and cohesion in flowers. 7. What is a pollen grain? Describe a mature pollen grain and a mature embryo-sac. What happens when a pollen grain germinates? 8. What is a placenta, and where do you find it? Describe the different types with sketches and examples. 9. Draw a neat diagram of an anatropous or orthotropous ovule, and label the parts. 10. Describe, with sketches, the common forms of ovules. 11. Write notes on any five of the following: panicle, helicoid, verticillaster, hypanthodium, hermaphrodite, gynophore, spathe, involucre, bilabiate, corona, epicalyx, pollinium, didynamous and apocarpous.

Chapters 10-11. 1. What is cross-pollination? How is it effected? 2. What are the characteristics of entomophilous and anemophilous flowers? 3. Describe the mode of pollination in sunflower, *Salvia*, maize and *Vallisneria*. 4. What are the contrivances met with in flowers to prevent self-pollination? 5. Give a detailed description of the process of fertilization in an angiosperm. What is double fertilization? 6. Write notes on cleistogamy, spur, anemophily, monoecious, dichogamy, protandry, egg-cell and synergids.

Chapters 12-14. 1. Describe the changes that take place in the ovule leading to its conversion into the seed. 2. How do you classify fruits? Describe the principal types. 3. Describe the fruits of pea, mustard, cotton, mango, tomato, apple, gourd and pineapple. 4. Describe in botanical terms the edible parts of the following fruits: apple, cashew-nut, cucumber, litchi, fig, pineapple, mango, coconut, jack and orange. 5. Give a concise account of how seeds and fruits are dispersed by wind. Of what importance is the distribution to the species? 6. Write notes on aril, perisperm, mesocarp, legume, capsule, berry, siliqua, pepo, sorosis and censor mechanism.

PART II HISTOLOGY

Chapter 1. 1. What is protoplasm? Where is it found in plants? What are the different kinds of movements exhibited by it? 2. Describe the structure of the nucleus, and state the main functions performed by it. 3. Describe the parts of a typical plant cell, and give a short account of their functions. 4. Describe the microscopic structure of starch grains and aleurone grains. How would you demonstrate their presence in the plant tissue? What kind of food do they represent? 5. What is cellulose? What modifications may it

undergo? How would you distinguish between cellulose and lignin? **6.** Enumerate and describe the most important reserve materials in plants. **7.** Give an account of the occurrence of mineral crystals in plants. **8.** Write short notes on middle lamella, vacuole, bordered pits, cystolith, cytoplasm, chromosome and raphides. **9.** Give an account of 'somatic cell division', and indicate the importance of the process.

Chapters 2-3. **1.** What is a tissue? What are the principal kinds of tissues found in plants? **2.** Where do you find a sieve-tube? Draw and describe its structure. **3.** Describe the apical meristem of a stem or a root, as seen in a longi-section. **4.** What are mechanical tissues? Describe their structure and distribution, as seen in transections of (*a*) sunflower stem and (*b*) maize stem. **5.** What are stomata? Describe their structure and functions. How do they behave when the atmosphere is dry? **6.** Describe the tissue-elements of a typical vascular bundle. What are the different types of vascular bundles? **7.** Write notes on tracheid, trachea, latex cell, sclerenchyma, collenchyma, endodermis and pericycle.

Chapters 4-6. **1.** Describe the anatomical structure of a dicotyledonous stem. **2.** Give a detailed description of the internal structure of a monocotyledonous stem. **3.** Describe the structure of a monocotyledonous root, as seen in a transverse section, and compare it with that of a dicotyledonous root. **4.** Describe the anatomical structure of a dorsiventral leaf, and state the functions of the different tissues met with in it. **5.** Write notes on hard bast, bicollateral bundle, conjunctive tissue, protoxylem, epiblema, mesophyll and palisade parenchyma.

Chapter 7. **1.** How does a dicotyledonous stem grow in thickness? **2.** Describe with neat sketches the origin and activity of cambium in a dicotyledonous root. **3.** What are annual rings? How are they formed? Describe their anatomical structure. **4.** How are cork and lenticel formed? Describe, with neat diagrams, their anatomical structure. State their functions.

PART III. PHYSIOLOGY

Chapters 1-4. **1.** What are the common types of soils? How are they formed? Give an account of their physical and chemical properties. **2.** What is humus? What is its utility in plant growth? How do you estimate the humus content of a soil? **4.** Enumerate the essential chemical elements that enter into the composition of a green plant. What are the methods usually followed to determine them? **5.** How does an ordinary green plant get its supply of carbon and nitrogen? What special means of nitrogen supply are found in, *Leguminosae*? **6.** What is osmosis? What role does it play in plant physiology? Devise an experiment to demonstrate it. **7.** Write notes on turgidity, plasmolysis, hydroponics, nitrification and nodule bacteria.

Chapter 5. **1.** What is root pressure? How do you demonstrate and measure it? Explain the significance of the process. **2.** What is transpiration? Devise an experiment to show the rate of transpiration from a twig. **3.** Devise an experiment to prove unequal transpiration from the two surfaces of a leaf. What is the significance of this

difference? **4.** Devise a simple experiment to show that a transpiring twig produces suction. Comment on the processes concerned. **5.** What do you understand by 'ascent of sap'? Discuss the main forces concerned in the process. **6.** Explain clearly how water enters, passes through and leaves a plant. **7.** What is the importance of transpiration in plant life? **8.** Write notes on manometer, bleeding, leaf-clasp, potometer, and exudation.

Chapters 6-9. **1.** Give a concise account of carbon-assimilation by green plants. **2.** How would you prove experimentally that submerged green plants assimilate carbon? **3.** How would you prove experimentally that light and carbon dioxide are indispensable for the formation of starch in photosynthesis? **4.** What are the external conditions necessary for photosynthesis? Clearly explain the influence of these conditions on the process. **5.** How would you prove experimentally that non-green parts of plants cannot photosynthesize? **6.** What are autotrophic and heterotrophic plants? Give a short account of various modes of nutrition of the latter. **7.** What special modes of nutrition are found in carnivorous plants? Describe a few common types. **8.** Describe the various organs and tissues which lay up stores of reserve food. What are the common forms of reserve food stored up in the seed? How are they utilized? **9.** Give a clear account of digestion and assimilation of food in green plants.

Chapters 10-11. **1.** What do you understand by respiration? How would you prove experimentally that plants respire? **2.** Describe the behaviour of plants deprived of oxygen, and demonstrate it by an experiment. **3.** Describe the nature of exchange of gases between the green plant and the atmosphere. **4.** Distinguish between respiration and photosynthesis. **5.** Write notes on the following: anaerobic respiration, fermentation, metabolism, respiroscope and zymase.

Chapters 12-14. **1.** What is growth? What is the influence of external conditions on growth? **2.** How would you measure growth in length of the stem? **3.** What is meant by irritability in plants? Give instances? **4.** Describe heliotropism, geotropism and hydrotropism, and demonstrate experimentally any one of these processes. **5.** Give a short account of hormones and vitamins occurring in plants. **6.** Write notes on heliotropic chamber, clinostat, auxanometer, and grand period of growth. **7.** Describe the methods by which the 'flowering' plants reproduce themselves vegetatively.

PART IV. ECOLOGY

Chapters 1-2. **1.** Define ecology. Enumerate the factors which influence ecological grouping of plants. Give examples. **2.** What are the characteristic features of hydrophytes? Cite familiar examples. **3.** What are halophytes? State what you know of their special characteristics. Give examples. **4.** Describe the characteristic features of xerophytes. Give examples. **5.** What is mangrove vegetation? Where do you find it in India? Describe, with examples, the main features of such a vegetation.

PART V. CRYPTOGAMS

Chapters 1-2. **1.** How do you classify cryptogams? State the differences between (a) Algae and Fungi, and (b) Bryophyta and Pteridophyta. **2.** Give a brief account of the structure and mode of reproduction in *Oscillatoria* and *Chlamydomonas*. **3.** Describe the life-history of *Ulothrix* or *Spirogyra*. **4.** Describe the life-history of *Oedogonium*. **5.** Write notes on zygospore, antherozoid, oogonium, coenocyte, isogamy, hormogonia and dwarf male.

Chapters 3-4. **1.** Give a brief account of bacteria, and state what you know of their harmful and beneficial effects. **2.** Give the life-history of any saprophytic fungus that you have studied. **3.** Compare the life-history of *Spirogyra* with that of *Mucor*. **4.** Some yeast cells are put into sugar solution. State and describe the changes that you may expect in (a) yeast cells and (b) sugar solution. **5.** Give a brief account of the life-history of *Agaricus*. **6.** Briefly describe some of the antibiotics that you have studied.

Chapter 5-6. **1.** Describe the life-history of *Riccia* or *Marchantia*, and trace the alternation of generations in it. **2.** What do you understand by alternation of generations? Illustrate your answer by reference to a moss plant or a fern plant. **3.** Describe the gametophytic generation of moss, or the sporophytic generation of fern. **4.** Describe the prothallus of fern. What phase does it represent in the life-history of the plant?

PART VI. GYMNOSPERMS

Chapter 1. **1.** Describe the life-history of *Cycas*. **2.** Describe the megasporophyll and microsporophyll of *Cycas*. **3.** Describe the ovule of *Cycas* as seen in a longitudinal section. **4.** Describe the mode of pollination and fertilization in *Cycas*.

PART VII. ANGIOSPERMS

Chapters 1-2. **1.** Define species, genus, family, variety and nomenclature, and illustrate them by suitable examples. **2.** Give diagnostic characters of the following families: *Cruciferae*, *Malvaceae*, *Papilionaceae* and *Cucurbitaceae*. Mention at least three economic plants belonging to each family. **3.** Give the outline of any modern system of classification of 'flowering' plants. **4.** Enumerate and explain the differences between dicotyledons and monocotyledons. **5.** Describe (a) the inflorescence and (b) the androecium of the following families: *Cruciferae*, *Compositae* and *Labiatae*. **6.** Mention the respective families where you find the following morphological characters: monadelphous, syngenesious, epipetalous, didynamous, apocarpous and inferior ovary. Give the main characteristics of any one of these families. **7.** Describe the family *Cucurbitaceae* or *Solanaceae* with necessary sketches and mention at least three examples of economic importance. **8.** Refer any five of the following plants to their respective families: *Ranunculus*, *Brassica*, *Hibiscus*, *Pisum*, *Rosa*, *Cucurbita*, *Solanum* and *Ocimum*, and give the characteristics of any one of these families.

Chapter 3. **1.** Give the main characteristics of the family *Palmaceae*, and mention at least three plants of economic importance belonging to it.

2. Describe *Liliaceae* with sketches and examples. How do you distinguish *Amaryllidaceae* from *Liliaceae*? 3. What is the economic importance of *Graminaceae*? Cite at least five examples. Give the important morphological characteristics of the family.

PART VIII. EVOLUTION AND GENETICS

Chapters 1-2. 1. What evidence can you cite in support of the theory of evolution? Clearly explain any two such evidences. 2. State briefly Darwin's contribution towards the idea of organic evolution. 3. Give a concise idea of some of the important theories advanced from time to time to explain organic evolution. 4. Explain Mendel's monohybrid cross? Tabulate the results up to F_2 generation. 5. Briefly explain Mendel's laws of inheritance. 6. Give in a tabulated form the results of Mendel's dihybrid cross. 7. What is the practical importance of Mendel's experiments? 8. How would you proceed to determine whether a plant possessing a particular dominant character is homozygous or heterozygous?

PART IX. ECONOMIC BOTANY

Chapters 1-2. 1. Describe the methods commonly employed for improvement of field crops. 2. What are cereals? Of what importance are they to human beings? Give a short account of at least two important cereals widely cultivated in India. 3. Give a short account of wheat, maize and *Sorghum*. Where are they cultivated in India? 4. Enumerate the important vegetable oils of India. What are the sources of these oils? Give a brief account of their uses. 5. Describe some important dessert fruits of India, and mention the edible parts in them. 6. What are the common timber trees of India? State their uses. 7. Write notes on the uses of the following plants: guinea grass, cardamom, cloves, ginger, garlic, pulses, potato, sugarcane and rubber. 8. What are the common beverages used in India? Where are they cultivated in India? Give a brief account of their manufacture and use.

APPENDIX II *Glossary of Names of Plants*

Botanical name in *italics*; English name in Roman; Indian name in CAPITALS—A. for Assamese, B. for Bengali, G. for Gujarati, H. for Hindi, K. for Kannada, M. for Malayalam, M'. for Marathi, O. for Oriya, P. for Punjabi, T. for Tamil, and T'. for Telugu.

- Abrus precatorius* (crab's eye or Indian liquorice)=A. LATUM-MONI; B. KUNCH; H. & P. RATTI; K. GULAGANJI; M. KUNNI; M'. GUNJ; O. KAINCHA, GUNJA; T. KUNDOO-MONY; T'. GURUGINJA
- Abutilon indicum*=A. JAPA-PETARI; B. PETARI; G. DABALI; H. KANGHI; K. THURUBI GIDA, SHREE-MUDRE GIDA, KISANGI; M. & T. PERINTHOTTY; M'. MUDRA; O. PEDIPEDIKA; P. PILI-BUTI; T'. THUTIRIBENDA
- Acacia arabica* (gum tree)=A. TORUA-KADAM; B. BABLA; G. KALOBAVAL; H. BABUL; K. KARI JALI; M. & T. KARUVELAM; M'. BABHUL; O. BABURI; P. KIKAR; T'. NALLATUMMA
- Acacia catechu* (catechu)=A., B. & M'. KHAIR; G. KHER; H. & P. KATHA, KHAIR; K. KAGGALLI, KACHU; M. KADARAM; O. KHAIRA; T. KADIRAM; T'. KHADIRAMU
- Acalypha indica*=B. MUKTO-JHURI; G. VANCHI KANTO; H. KUPPI; K. KUPPI GIDA, TUPPAKEERE; M. & T. KUPPAMANI; M'. KHOKALI; O. INDRAMARISHA; P. KOKALI KUPPAMANI
- Achryanthes aspera* (chaff-flower)=A. UBTISATH; B. APANG; G. SAFED AGHEDO; H. LATJIRA; K. UTTARANI; M. KATALADY; M'. AGHADA; O. APAMARANGA; P. PUTHKANDA, KUTRI; T. NAHIROORVY; T'. ATTAREN
- Acorus calamus* (sweet flag)=A. & H. BOCH; G. GODAVAJ; K. BAJE; M. VAYAMBU; M'. WEKHAND; O. BACHA; P. WARCH, BOJ, BARI; T. VASAMBOO; T'. VASA
- Adhatoda vasica*=A. BANHAKA; B. BASAK; G. ADULSO; H. ADALSA; K. ADUSOGE; KURCHI GIDA, ADDALASA; M. ADALODAKAM; M'. ADULSA; O. BASANGA; P. BANSA SUBJ, BASUTI; T. ADATODAY; T'. ATARUSHAMMU
- Aegle marmelos* (wood-apple)=A. & B. BAEL; G. BILVA-PHAL; H. SIRIPHAL; K. BILVA PATRE; M. KOOVALAM; M'. BEL; O. BELA; P. BIL; T. VILVAMARAM; T'. BILAMBU
- Agrave americana* (American aloe or century plant)=B. & H. KANTALA; G. JANGLI-KANVAR; K. KATTALE; M. NATTUKAITA; M', GHAYPAT; O. BARABARASIA; P. WILAYATI KANTALA; T. ANAKUTTHILAI; T'. BON-THARAKASI
- Albizia lebbek* (siris tree)=A., B., H., M'. & P. SIRISH; K. SHIRISHA BAGE, HOMBAGE; G. PITO-SARSHIO; M. VAGA; O. SIRISA; T. VAGAI; T'. DIRISANA
- Allium cepa* (onion)=A. PONORU; B., H. & P. PIYAZ; G. DUNGARI; K. NEERULLI, ULLAGADDI; M. ULLI; M'. KANDA; O. PIAJA; T. VEN-GAYAM; T'. YERRAGADDA
- Allium sativum* (garlic)=A. NAHARU; B. RASUN; G. LASAN; H. & P. LASHUN; K. BELLULLI; M. VELUTHULLI; M'. LASUN; O. RASUNA; T. VELLAIFOONDU; T'. TELLAGADDA
- Alocasia indica*=A. & B. MANKACHU; G. ALAVU; H. MANKANDA; K. MANAKA; M'. ALU; O. MANASARU; P. ARVI
- Aloe vera* (Indian aloe)=A. CHALKUNWARI; B. GHIRITAKUMARI; G. KUNVAR; H. GHIKAVAR; K. LOLESARA; M. KATTARVAZHA; M'. KORPHAD; O. GHEEKUANRI; P. KAWARGANDAL, GHIKUAR; T. KUTTILAI
- Alstonia scholaris* (devil tree)=A. CHATIAN; B. CHHATIM; H. CHATIUM; K. SAPTA PARNA, MADDALE, KODALE; M. EZHILAMPALA; M'. SATVIN; O. CHHATIANA, CHHANCHANIA; P. SATONA; T. ELJLAI-PILLAI; T'. EDAKULAPALA
- Amarantus spinosus* (amaranth)=A. KATA-KHUTURA; B. KANTA-NATE; G. TANJALJO; H. & P. CHULAI; K. MULLU KEERE (or HARIVE) SOPPU; M. MULLANCHEERA; M'. KATE MATH; O. KANTANEUTIA, KANTA-MARISHA; T. MULLUKKERAI; T'. MUNDLA THOTAKURA
- Amorphophallus campanulatus* = A. & B. ol; G. & M'. SURAN; H. KANDA; K. SUVARNA (or CHURNA) GEDDE; M. CHAENA; O. OLUA; P. ZAMIN KANDA; T. KARUNAKILANGU; T'. THIYA KANDHA
- Anacardium occidentale* (cashew-

- nut*)=A. KAJU-BADAM; B. HIJLI-BADAM; G., H., M'. & P. KAJU; K. GODAMBI, GERUPAPPY; M. KASHUMAVU; O. LANKA BADAM; T. MUNDIRI; T'. JIDIMAMIDI
Andrographis paniculata=A. KALPATITA; B. & H. KALMEGH, MAHATITA; G. KIRYATO; K. NELA BEVU, KALA MEGHA; M. KIRIYATHITHU; M'. PALEKIRAIET; O. BHUINIMBA; P. CHARAITA; T. NELAVEMBU
Annona reticulata (bullock's heart)=A. ATLAS; B. NONA; G., H., M'. & P. RAMPHAL; K. RAMA PHALA; M. ATHA; O. NEUA, BADHIALA; T. & T'. RAMSITA
Annona squamosa (custard-apple)=A. ATLAS; B. ATA; G. & M. SITAPHAL; H. & P. SHARIFA, SITAPHAL; K. SEETHIA PHALA; M. SEEMA-ATHA; T. & T'. SEETHA
Anthocephalus cadamba=A., B., H. & P. KADAM; G. & O. KADAMBA; K. KADAMBA MARA, KADAVALA; M. KADAMBU; M'. KADAMB
Arachis hypogaea (peanut or groundnut)=A., B. & O. CHINA-BADAM; G. MAFFALI; H. & P. MUNGPHALI; K. NELAGADELA, SHENGA, KALLEKAI; M. & T. NILAKKADALAI; M'. BHUI-MUG; T'. VERU SANAGA
Areca catechu (areca- or betel-nut)=A. TAMBUL; B., G., M'. & P. SUPARI; H. KASAILI; K. ADIKE; M. ADAKKKA; O. GUA; T. PAKKU; T'. POKA
Argemone mexicana (prickly poppy)=A. KUHUM-KATA; B. SHEALKANTA; G. DARUDI; H. PILA-DHUTURA; K. DATTURADA GIDA, ARISINA UMMATTI; M. SWARNAKSHEERI; M'. PIWALA DHOTRA; O. AGARA; P. KANDIARI; T. BRAHMADANDU; T'. DATTURI
Aristolochia gigas (pelican flower)=A., B. & O. HANSHA-LATA; K. KURI GIDA; M. GARUDAKRODI; M'. POPAT VEL; P. BATKH PHUL; T. ADATHINA-PALAI
Artobotrys odoratissimus=A. KO-THALI-CHAMPA; B., G. & H. KANTALI-CHAMPA; K. MANORANJINI, KANDALA SAMPIGE; M. & T. MANO-RANJINI; M'. HIIRWA CHAPHA; O. CHINI-CHAMPA; P. CHAMPA; T'. MANORANJITHAM
Artocarpus integrifolia (jack tree)=A. KOTHAI; B. KANTHAL; G. MAN-PHANASA; H. KATAHAR; K. HALASU; M. & T. PILA; M'. PHANAS; O. PANASA; P. KATAR
Asparagus racemosus=A. SHATMUL; B. SATAMULI; H. & P. SATAWAR; K. SHATAVARI; O. CHHATUARI; M., M'. & T. SATHAVARI; T'. SADA-VARI
Averrhoa carambola (carambola)=A. KORDOI-TENGA; B. KAMRANGA; G. KAMARAKHA; H. & P. KAMRAKH; K. KAMARAXI, KAMARAK; M. IRIMPANPULI; M'. CAMARANGA; O. KARMANGA; T. KAMARANKAI; T'. TAMARTA
Azadirachta indica (margosa)=A. MOHA-NEM; B., H. & P. NJM, NIMBA; G. LIMBA; K. OLLE BEVU; M. VEPPU; M'. KADU LIMB; O. NIMBA; T. VEMBU; T'. VEPPAI
Baccaurea sapida=A. LETEKU; B. LATKAN; H. LUTKO; K. KOLI KUKKE; P. KALA BOGATT
Bambusa tulda (bamboo)=A. BAHN; B., H. & P. BANS; G. KAPURA; K. HEBBIDIRU, UNDE BIDIRU; M. MULAH; M'. BAMBOO; O. BAUNSA; T. MULAI
Basella rubra (Indian spinach)=A. PURAI; B. PUIN; H. O. & P. POI; K. KEMPU BAYI BASALE; M. SAMPARCHEERA; M'. VELBONDI; T. SAMBARKEERAI
Batatas edulis (sweet potato)=A. & B. MITHA-ALOO; G. SHAKKARIA; H. & P. SHAKKARAND; K. GENASU; M. MADHURAKI ZHANGU; M'. BATALA; O. CHINI-ALOO, KANDAMULA; T'. GENUSU
Bauhinia variegata (camel's foot tree)=A., B. & M'. KANCHAN; G. KOVIDARA; H. & P. KACHNAR; K. ULIPE, BILI MANDARA; M. MANDARUM; O. KANCHANA; T. TIRUVATTI; T'. ADAVIMANDARA
Benincasa cerifera (ash gourd)=A. KOMORA; B. CHAL-KUMRA; G. KOHWLA; H. & P. PETHA; K. FOODU GUMBALA; M. KUMPALAM; M'. KOHALA; O. PANI-KAKHARU; T. KUMPALY; T'. PULLA GUMMUDI
Beta vulgaris (beet)=A. BEET-PALENG; B. PALANG-SAK; G. & M'. BEET; H. & P. CHUKANDAR; K. BEET ROOT; O. PALANGA SAGA, BEET
Bryophyllum sensitivum (sensitive-wood-sorrel)=A. & B. BAN-NARANGA; G. JAHRERA; H. LAJALU; K. HORA MUNI; M. MUKKUTTI, THINDANAZHI; M'. LAJARI
Blumea lacera=A. KUKUR-SHUTA; B. KUKUR-SONGA; G. KALAR; H. & P. KOKRONDA; K. GANDHART GIDA; M'. BURANDO; O. POKA-SUNGA; T. KATUMULLANGI
Boerhaavia diffusa (hogweed)=A. PONONUA; B. & M'. PUNARNAVA; G. GHETULI; H. THIKRI, GADHA-

- PURVA*; K. BALAVADIKE, GONAJALI; RAKTA FUNARNAVA; M. THAZHUTHAMA; O. GHODAPURUNI; P. BISKHAPRA, ITSTI; T. MUKKARATAI; T'. FUNARNABA
- Borassus flabellifer* (palmyra-palm) = A. & B. TAL; G. & M'. TAD; H. & P. TAR; K. TALE MARA, TATTI NUNGU; M. KARIMPANA; O. TALA; T. PANAI; T'. THADI
- Brassica campestris* (mustard) = A. SARIAH; B. SARISHA; G. SAFEDRAI; H. & P. SARSON; K. SASIVE; M. KATUKU; M'. MOHORI; O. SOROSIA; T. KARUPPUKKADUGU
- Bryophyllum pinnatum* (sprout-leaf plant) = A. PATEGAZA, DUPORTENCA; B. PATHURKUCHI; H. ZAKHM-I-HAYAT; K. KADU BASALE; M'. PANPHUTI; O. AMARPOT; P. PATHUR-CHAT; T. RANAKALLI; T'. SIMAJAMUDU
- Caesalpinia pulcherrima* (dwarf gold mohur or peacock flower) = A. SWARNAKANTI; B. RADHACHURA; G. SANDHESHARO; H. GULETURA; K. KENJIGE GIDA, RATNA GANDHI; M. RAJMALLI; M'. SHANKASUR; O. KRUSHNACHUDA, CODIBANA; P. KRISHNACHURA; T. MAYIRKONRAI; T'. TURAYI
- Cajanus cajan* (pigeon pea) = A. RAHAR-MAH; B. ARAHAR; G. TUWARE; H. RAHAR; K. THOGIKAL; M. THUVARA; M'. TUR; O. HARADA; T. THOVARAY; T'. KANDULU
- Calotropis gigantea* (madar) = A. AKON-GOCH; B. AKANDA; G. AKADO; H. & P. AK; K. EKKADA GIDA; M. & T. ERUKKU; M'. RUI; O. ARKA; T'. JILLEDU
- Cannabis sativa* (hemp) = A., B., H. & P. BHANG, GANJA; G., P. & T. GANJA; K. GANJA GIDA, BHANGI; M. KANCHAVU; M'. BHANG; O. BHANGA, GANJEI; T'. GANJA CHETTU
- Cardiospermum halicacabum* (balloon vine) = A. KOPALPHOTA; B. KAPALPHUTKI, SHIBJHUL; G. KARODIO; K. BEKKINA BUDDA GIDA, ERUMBALLI; M. VALLIYUZHINJA; M'. KAPALPHODI; O. PHUTPHUTKIA; P. HAB-UL-KULKUL; T. MODAKATHAN; T'. BUDDAKAKKIRA, KASARITIGE
- Carissa carandas* = A. KORJA-TENGA; B. KARANJA; H. & P. KARONDA; K. KAVALI GIDA, KARANDA; M. ELIMULLU; M'. KARVANDA; O. KHIRAKOLI; T. KALAKKAI; T'. KALIVI
- Carthamus tinctorius* (safflower) = A. & B. KUSUM-PHUL; G. KUSUMBO;
- H. & P. KUSAM; K. KUSUBI, KUSUME; M. SINDOORAM; M'. KARDAI; O. KUSUMA; T. & T'. KUSUMBA
- Carum copticum* = A. JONI-GUTI; B. JOWAN; G. AJAMO; H. & P. AJOWAN; K. OMU, AJAWANA; M. AYAMODAKAM; M'. OWA; O. JUANI; T. OMAM; T'. OMAMU
- Cassia fistula* (Indian laburnum) = A. SONARU; B. SHONDAL; G. GAR-MALA; H. & P. AMALTASH; K. KAKKE GIDA, HONNAVARIKE; M. & T. KONNAI; M'. BAHAWA, O. SUNARI
- Cassia sophera* = A. MEDELUA; B. KALKASUNDA; G. KASUNDARI; H. & P. KASUNDA; K. KASAMARDA; M. PONNARAN OF PONNAM-THAKARA; M'. KALA-KASBINDA; O. KUSUNDA; T. PONNAVEERAN
- Cassytha filiformis* = B. AKASH-BEL; H. AMARBELI; K. AKASHA BALLI, MANGANA UDIDARA; M. AKASA-VALLI; M'. AKASHVALLI; O. AKASHA BELA; P. AMIL, AMARBELI
- Casuarina equisetifolia* (beef-wood tree) = A., B., H. & P. JHAU; G. VILAYATI SARU; K. SARVE MARA, GALL MARA; M. CHOOLAMARUM, KATTADIMARUM; M'. KHADSHERANI; O. JHAUN; T. SAVUKKU; T'. SARAVU
- Celosia cristata* (cock's comb) = A. KUKURA-JOA-PHUL; B. MORAG-PHUL; G. LAPADI; H. JATADHARI; K. MAYURA SHIKHI; M. KOZHI-PULLU; M'. KOMBADA; O. GANJA-CHULIA; P. KUKUR-PHUL
- Centella asiatica* (Indian pennywort) = A. MANIMUNI; B. THUL-KURI; G. KAR BRAHMI; H. & P. BRAHMI-BOOTI; K. ONDELAGA, BRAHMI SOPPU; M. KODANGAL, KOTAKAN; M'. BRAHMI; O. THAL-KUDI; T. VULLARAI
- Cestrum nocturnum* (queen of the night) = A. & B. HAS-NA-HANA; H. RAT-KI-RANI; K. RATRI RANI HOOVU
- Chrysopogon aciculatus* (love thorn) = A. BON-GUTI; B. CHOR-KANTA; K. GANJICARIKE HULLU; O. GUGUCHIA; P. CHOR-KANDA
- Cicer arietinum* (gram) = A. BOOT-MAH; B. CHOLA; G., H. & P. CHANA; K. KADALE, CHANA; M. & T. KADALAI; M'. HARABHARA; O. BUTA; T'. SANIKALU
- Cinnamomum camphora* (camphor) = A. & B. KARPUR; G., H. & M'. KAPUR; K. KARPURADA GIDA; M. KARPPURAVRIKSHAM; O.

- KARPURA*; P. KAFUR; T. KARUPPURAM; T'. KAPPURAMU
Cinnamomum tamala (bay leaf)=A. TEJPAT, MAHPAT; B. TEZPATA; G. & H. TEZPAT; K. KADU DALCHINNI; M'. TAMAL; O. & P. TEJPATRA; T. TALISHAPATTI; T'. TALLISHAPATRI
Cinnamomum zeylanicum (cinnamon)=A., B., G., M', O. & P. DALCHINNI; H. DARCHINNI; K. DALCHINNI, LAVANGA CHAKKE; M. & T. ILLAVANGAM; T'. LAVANGAMU
Cissus quadrangularis=A., B. & H. HARHJORA; K. MANGARA VALLI, SANDU BALLI; M. PIRANTA; M'. KANDAWEL; O. HADAVANGA; P. GIDAR-DAK, DRUKRI; T. PIRANDAI; T'. NALLERU
Citrullus vulgaris (water melon)=A. KHORMUJA; B. TARMUJ; G. KARIGU; H. & P. TARBUZA; K. KALLANGADI BALLI; M. & T. KUMMATTIKKAI; M'. KALINGAD; O. TARABHUJA
Citrus aurantifolia (sour lime)=A. NEMU-TENGA; B. KAGJI-NEBU; G. LIMBU; H. NIMBOO; K. NIMBE; M. CHERUNARAKAM; M'. KAGADI LIMBU; O. LEMBU; P. GALGAL; T. ELIMICHHAM; T' NIMMAPANDU
Citrus grandis (pummelo or shaddock)=A. REBAB-TENGA; B. BATABI-NEBU; G. OBAKOTRU; H. & P. CHAKOTRA; K. CHAKKOTHIA; M. BAMBLEENARAKAM; M'. PAPANAS; O. BATAPI; T. BAMBALMAS
Citrus reticulata (orange)=A. KAMALA-TENGA; B. & O. KAMALA; G. SUNTRA; H. NARANGI; K. KITTALE; M. NARAKAM; M'. SANTRA; P. SANCTR; T. NARANGAM; T'. NARANJI
Clitoria ternatea (butterfly pea)=A., B. & O. APARAJITA; G. GARANI; H. APARAJIT; K. GIRI KARNAIKE, SATUGADA GIDA; M. SANKHU-PUSHPAM; M'. GOKARNA; P. APARAJIT, NILI LOEL; T. KAKKATAN; T'. SANGA-PUSHPAM
Coccinia cordifolia=A. BELIPOKA; B. TELAKUCHA; H. BHIMBA; K. THONDE KAYI, KAGE DONDE; M. KOVEL; M'. TONDALE; O. KUNDURI, KAINCHIKAKUDI; P. GHOL; T. KOVARAI; T'. KAKIDONDA
Colocasia esculenta (taro)=A. & B. KACHU; H. & P. KACHALU; K. KESAVINA GEDDE, SAVE GEDDE; M. CHEMPU; M'. KASALU; O. SARU; T. SAMAKILANGOO; T'. CHEMA
Coriandrum sativum (coriander)=A., B., H., O. & P. DHANIA; G. DHANE; K. KOTHAMBARI, HAVEEJA;
- M. & T. KOTTAMALLI; M'. KOTHIM-BIR; T'. DHANIYALU
Crotalaria juncea (Indian or sunn hemp)=A. SHON; B. SHONE; G., H. & P. SAN; K. APSENA-BU, SANNA SENABU; M. THANTHALAKOTTI; M'. KHULKHULA; O. CHHANAPATA; T. SANAPPAI; T'. JANNAMU
Crotalaria sericea (rattlewort)=A. GHANTA-KORNA; B. ATASHI; H. JHUNJHUNIA; K. GLICILI GIDA; M. THANTHALAKOTTI; M'. GHAGRI; O. JUNKA; P. JHANJHANIA
Cucumis melo (melon)=A. BANGI; B. PHUTI; G. TARBUCH; H. & P. KHBARBUZA, PHUTI & KAKRI; K. KARABUZA, KEKKARIKE; M. & T. THANNIMATHAI; M'. KHBARBUJ; O. KHBARBUJA
Cucumis sativus (cucumber)=A. TIANH; B. SASHA; G. KAKRI; H., M., & P. KHIRA; K. SOUTHE KAYI; M. MULLENVELLARI; O. KAKUDI; T. MULLUVELLARI
Cucurbita moschata (sweet gourd)=A. RONGA-LAU; B. MITHA-KUMRA; H. MITHA-KADDU; K. SEEGUMBALA; M. MATHANGAI; M'. KALA BHOPALA; O. MITHA KOKHARU; P. HALWA-KADDU; T. POOSANIKAI
Curcuma domestica (turmeric)=A. HOLODHI; B. HALOOD; B. & M'. HALAD; H. & P. HALDI; K. ARISINA; M. KUVA; O. HALADI; T. MANJAL; T'. PASUPU
Cuscuta reflexa (dodder)=A. AKASHI-LOTA, RAVANAR-NARI; B. SWARNA-LATA; G. AKASWEL; H. AKASH-BEL; K. BADANIKE, BANDA-LIKE, MUDITALE; M'. AMAR VEL; O. NIRMLI; P. AMARBEL
Cynodon dactylon (dog grass)=A. DUBORI-BON; B. DURBA-GHAS; G. DURVA; H. & P. DOOB; K. GARIKE HULLU, KUDIGARIKE; M. & T. ARUGAMPULLU; M'. HARALI; O. DUBA GHASA; T'. GERICHA GADDI
Dalbergia sissoo (Indian redwood)=A. SHISHOO; B. SISOO; G. SHISHAM; H. & P. SHISHAM, TAHLI; K. BIRADI, BINDI, SHISSU; M. VEETI; M'. SHISAVI; O. SISU
Datura fastuosa (thorn-apple)=A. DHOTURA; B. DHUTRA; G. DHA-TOORA; H. & P. DHUTURA; K. DATTURA, UMMATTI; M. UMMAM; M'. DHOTRA; O. DUDURA; T. OOMMATHAI; T'. UMMATHA
Delonix regia (gold mohur)=A. & B. KRISHNACHURA; G., H., M'. & P. GULMOHR; K. SEEME SAN-KESWARA, KEMPU TURAI; M. MARA-

- MANDARAM; O. RADHACHUDA; T. MAYILKONNAI
Dillenia indica = A. OU-TENGA; B., H. & P. CHALTA; G. CARAMBAL; K. MUCHHILU, KALTEGA; M. VAL-LAPUNNA; M'. KARAMAL; O. OU; T. UVATEKU; T'. UVVA
Dioscorea bulbifera (wild yam)=A. GOCH-ALOO; B. GACHH-ALOO; G. SAURIYA; H. & P. ZAMINKHAND; K. HEGGENASU, KANTA GENASU; M. KATTUKACHIL; M'. KADU KAR-ANDA; O. DESHI-ALOO, PITA-ALOO; T. KATTUKKILANGU; T'. CHEDU-PADDUDUMPA
Dolichos lablab (country bean)=A. UROHI; B. SHIM; G. AVRI; H. & P. SEM; K. AVARE BALLI; M. SIMA-PAYARU; M'. PAVATA, VAL; O. SIMA; T. AVARAI; T'. CHIK-KUDI
Duranta plumieri = A. JEORA-GOCH; B. DURANTA-KANTA; H. & P. NIL-KANTA; K. DURANTHA KANTI; M'. DURANTA; O. BILATI KANTA, BEN-JUATI
Eclipta alba=A. KEHORAJI; B. KESARAJ; G., H. & P. BHANGRA; K. GARUGADA GIDA, GARUGALU; M. & T. KAYYANYAM, KAITHONNI; M'. MAKAA; O. KESHGDURA
Eleusine coracana=B. & H. MAR-HUA; G. NAVTO; K. RAGI; M. PANJAPPULLU; M'. NACHANI; O. MANDIA; P. KODRA, MANDWA; T. KOLVARAKU; T'. RAGI
Enhydra fluctuans=A. HELACHI-SAK, MONOA-SAK; B. & P. HALENCHA; H. HARUCH; M'. HARKUCH; O. HIDIMICHI, PANI SAGA
Entada scandens (nicker bean) = A. GHILA; B., H., O. & P. GILA; G. SUVALI-AMLI; K. GARDALA, HALLE-KAYI BALLI; M. KAKKUVALLY; M'. GARBI; T. CHILLU; T'. GILLATIGAI
Enterolobium saman (rain tree)=A. SIRISH GOCH; K. MALE MARA; M. URAKKAM-THOONGIMARAM; M'. SAMAN; O. BADA GACHHA CHAKUNDA, BANA SIRISHA
Ervatamia divaricata=A. KOTHONAPHUL; B. & M'. TAGAR; H. & P. CHANDNI; K. NANDI BATLU, NANJA BATLU; M. & T. NANTHIAR VAT-TAM; O. TAGARA
Erythrina indica (coral tree) = A. MODAR; B. MANDAR; G. PANARAWAS; H. PANJIRA; K. HARIVANA, VARJIPE; M. & T. MURUKKU; M'. PANGARA; O. PALDHUA; P. DAR-AKHT FARID, PANGRA
Euphorbia antiquorum = B. BAJ-BARAN; G. TANDHARI; K. BONTE GALLI, CHADARA GALLI; M. CHATHI-RAKKALLI; M'. CHAUDHARI NIWDUNG; O. DOKANA SIJU; P. DANDA THOR, TIDHARA SEHUD; T. SHAD-RAIKALLI; T'. BONTHAKALI
Euphorbia nerifolia A. SIJU; B. MANSHA-SIJ; G. THOR; H. SJ; K. ELE GALLI; M. & T. ILAKKALLI; M'. CHAUDHARI NIWDUNG; O. PATARA SIJU; P. GANGICHU; T'. AKUJEMUDU
Euphorbia pulcherrima (poinsettia)=A. LAL-PAT; B., M'. & P. LAL-PATA; K. POINSETTIA GIDA; O. PANCHUTIA; P. LAL-PATTI; T. MAYILKUNNI
Ferula foetida (asafoetida)=A., B., G., H., M'. & P. HING; K. INGU, HINGU; M. KAYAM; O. HENGU
Ficus bengalensis (banyan)=A. BORGOC; B. BOT; H. & P. BARH; G. & M'. WAD; K. AALADA MARA; M. PEERALU; O. BARA; T. AALU-MARAM; T'. MARRI
Ficus glomerata (fig.)=A. DIMORU; B. DUMUR; G. UMBARO; H. & P. GULAR; K. ATHI; M. & T. ATH-THYMAR; M'. UMBAB; O. DIMURI; T'. BODDA
Ficus religiosa (peepul)=A. ANHOT; B. ASWATTHA; G. JARI; H. & P. PIPAL; K. ARALI, ASWATHA; M. ARAYALU; M'. PIMPAL; O. ASWA-THA; T. ARASU; T'. ASWATHAM
Foeniculum vulgare (anise or fennel)=A. GUA-MOORI; B. PAN-MOURI; G. WARIARI; H. & P. SAUNF; K. DODDA JEERIGE, DODDA SOMPU; M'. BADISHEP; O. PAN MOHURI
Gardenia florida (cape jasmine)=A. TOGOR; B., H. & P. GANDHARAJ; G. DIKAMALI; K. SUVASANE-MALLE; M'. GANDHRAJ; O. SUGAN-DIHARAJ
Gloriosa superba (glory lily)=A. & B. ULAT-CHANDAL; G. & M'. KHADYANAG; H. KALLARI, KUL-HARI; K. SHIVASHAKTI, LANGU-LIKA; M. MANTHONNI, PARAYAN-POOVA; O. PANCHANGULIA; P. GURHPATNI, KULHARI; T. KALAPAI-KILANGU; T'. AGNISIKA
Gynandropsis gymandra=A. BHUT-MUIA; B. HURHURE; G. ADIYA-KHARAM; H. HURHUR; K. NARAM-BELE SOPPU; M. KATTUKATUKU; M'. TILVAN; O. ANASORISIA, SADA HURHURIA; P. HULHUL; T. NAIKADUGU; T'. VAMINTA
Helianthus annuus (sunflower) = A. BELL-PHUL; B. & O. SURYAMUKHI; G. SURYAMUKHI; H. & P. SURAJ-MUKHI; K. SURYAKANTHI; M., T. & T'. SURIYAKANTI; M'. SURYA-PHUL

- Hibiscus esculentus* (lady's finger)= A., O. & M'. BHENDI; B., H. & P. BHINDI; G. BHINDA; K. BHENDE KAYT; M. & T. VENDAKKA; T'. BENDA
- Hibiscus mutabilis*= A. & B. STHAL-PADMA; G. UPALASARI; H. GULLAJAIB; K. BETTA DAVARE, KEMPU SURYAKANTHI; M. CHINAPPARATTI; M'. GULABI BHENDI; O. THALAPADMA; P. GUL-I-AJAIB; T. SEM-BARATTAI
- Hibiscus rosa-sinensis* (China rose or shoe-flower)= A. JOBA; B. JABA; G. JASUNT; H. GURHAL, JASUM; K. KEMPU DASAVALA; M. CHEMPARATHY; M'. JASWAND; O. MANDARA; P. GURHAL, JIA PUSHPA; T. SAMBATHOOCHEDI; T'. DASANI
- Hibiscus sabdariffa* (rozelle)= A. MESEKA-TENG; B. MESTA; H. & P. PATWA; K. KEMPU PUNDRIKE; M. PULICHI; M'. LAL-AMBADI; O. KHATA KAUNRIA
- Hiptoe madablotia* = A. MADHOI-LOTA; B. & O. MADHABI-LATA; G. MADHAVI; H. MADHU-LATA; K. MADHAVI LATHE; M. SITAPU; M'. MADHUMALATI; P. MADULATA, BAN-KAR; T. KURUKKATTI, MADAVI
- Holarrhena antidysenterica*= A. DUD-KHORI; B. KURCHI; G. INDRAJAVANU; H. KARCHI; K. KODACHAGA, KODAMURUKA, KORJU; M. KODAKAPPALA; M'. KUDA; O. FITA KORUA; P. INDER JAU, KAWAR
- Impatiens balsamina* (balsam)= A. DAMDEUKA; B. DOPATI; H. GUL-MENDI; K. GOURI HOOVA, BASAVA-NA PADA; M. & T. BALSAM; M'. TERADA; O. HARAGOURA; P. MA-JITI, BANTIL, PALLU
- Ipomoea reptans* (water bindweed) = A. KALMAU; B. & H. KALMI-SAK; G. NALNIPHAJI; K. BILI HAMBU; M. KALAMBI, NAL; O. KALAMA SAGA; P. NALI, KALMI SAG
- Ixora coccinea*= A. & B. RANGAN; H. GOTAGANDHAL; K. MALE HOO GIDA, KEPALE; M. & T. CHETHTHY, THEITY; M'. MAKADI; O. KHADIKA PHULA, RANGANI; P. RUNGAN
- Jasminum sambac* (jasmine)= A. JUTI-PHUL; B. & H. BELA; G. BAT-MOGRI; K. GUNDU MALLIGE; M. MULLA; M'. MOGARA; O. MALLI
- Jatropha gossypifolia* = A. PHOTERA; B., H. & P. LAL-BHARENDI; K. CHIKKA KADU HARALU, HATHI YELE HARALU; M'. VILAYATI ERAND; O. NALI BAIGABA, VERENDA; T. ADALAI; T'. NEPALEMU
- Jussiaea repens*= A. TALJURIA; B.
- KESSRA; K. NEERU DANTU, KAVAKULA; M. NIRGRAMPU; M'. PAN LAWANG; T. NIRKIRAMPU; T'. NIRUYAGNIVENDRAMU
- Lagenaria siceraria* (bottle gourd)= A. JATT-LAU; B. & O. LAU; H. LAUKI; K. EESUGAYI BALLI, HALU GUMBALA; M. & T. CHORAKKAI; M'. DUDHYA BHOPALA; P. GHIIYA
- Lagerstroemia flor-reginae*= A. AJAR; B., H. & P. JARUL; K. HOLE DASAVALA, CHELLA, BENDEKA; M. NIRVENTEKKU; M'. TAMAN; O. PATOLI; T. PUMARUTHU
- Lantana indica* (lantana)= G. GHANIDALIA; K. LANTAVANA GIDA, HESIGE HOOVA; M. PUCHEDI; M'. GHANERI; O. NAGA-AIRI; P. DESI LANTANA; T. ARIPPUS; T'. LANTANA
- Lathyrus sativus* = A. KOLA-MAH; B. H. & O. KHESARI; G. MATER; K. CHIKKA TOGARI, VISHA TOGARI, KESARI BELE; M'. LAKH; P. KISARI DAL
- Lens culinaris* (lentil)= A. MOSOOR-MAH; B. MASURI; G. MASURIDAL; H., M'. & P. MASUR; K. MASURU BELE, LENTEL GIDA; O. MASURA
- Leonturus sibiricus* = A. RONGADORON; B. DRONA; H. HALKUSA, GUMA; O. BHUTA-AIRI, KOILIKHIA
- Leucas linifolia*= A. DORON, DURUMPHUL; B. SWET-DRONA; G. JHINA-PANNI KUBO; H. CHOTA-HALKUSA; K. GANTU THUMBE, KARJALI GIDA; M. THUMPA; M'. DRONAPUSHPI, GUMA; O. GAISA; P. GULDODA; T. THUMPAI; T'. TAMMA CHETTU
- Limonia acidissima* (elephant-apple) = A. & B. KATH-BAEL; G. KOTHA; H. & P. KAITHA; K. KADU BILVA PATRE, NAYI BELA; M. BLANKA; M'. KAWATH; O. KAINTHA; T. VELAMARUM; T'. VELANGA
- Linum usitatissimum* (linseed)= A. TICHI; B. TISII; G. JAVA; H. & P. ALSHI; K. SEEME AGASE BEEJA; M'. JAWAS; O. PESI; T. AALIVIRAI
- Loranthus longiflorus* = A. ROGHUMALA; B. MANDA; G. VANDO; H. BANDA; K. SIGARE BADANKE; M. ITHTHIL; M'. BANDGUL; O. MALANGA, MADANGA; P. PAND; T. PULLURUVI; T'. BAJINNIKI, BADANIKA
- Luffa acutangula* (ribbed gourd)= A. JIKA; B. JHINGA; G. SIROLA; H. & P. KALI-TORI; K. HEERE BALLI; M. PEECHIL, PEECHINGAI; M'. DODAKA; O. JAHNI; T. PEE-CHANNA
- Luffa cylindrica* (bath sponge or loofah)= A. BHOL; B. DHUNDUL;

- H. & P. GHIIYA-TORI; M'. GHOSALE; O. PITA TARADA
Martynia diandra (tiger's nail)=A. & B. BAGH-NAKHI; G. VICHCHIDA; H. SHERNUI; K. HULI NAKHA, GARUDA MOOGU; M. & T. KAKKACHUNDU, PULINAGAM; M'. WINCHOURI; O. BAGHA NAKHI; P. HATHAJORI; T'. GARUDA MUKKU
Michelia champaca = A. & P. CHAMPA-PHUL; B. SWARNACHAMPA; G. RAE CHAMPAC; H. CHAMPACK; K. SAMPIGE; M. & T. CHEMPAKAM; M'. SONCHAPHA; O. CHAMPA; T'. SAMPAKA
Mimosa pudica (sensitive plant)= A. LAJUKI-LOTA; B. LAJJABATILATA; G. LAJJAWANTI; H. & P. LAJWANTI; K. MUTTIDARE MUNI, MUDUGU DAVARE; M. THOTTALVADI; M'. LAJALU; O. LAJAKULLI, LAJKURI; T. THOTTASINIGI; T'. PEDDA NIDRAKANTHA
Mirabilis jalapa (four o'clock plant or marvel of Peru)=A. GODHULI-GOPAL; B. KRISHNAKOLI; H. GULABBAS; K. SANJE TALLIGE, GULBAKSHI, BHADRAKSHI; M. NALUMANICHEDI; M'. GULBAKSHI; O. RANGANI, BADHULI; P. GUL-E-ABBASI; T. ANDIMANDARAI; T'. CHANDRAKANTA
Momordica charantia (bitter gourd) =A. TITA-KERALA; B. KARALA & UCHCHE; G., H. & P. KARELA; K. HAGALA KAYI; M. & T. PAVAL, PAVAKKAI; M'. KARLE; O. KALARA; T'. KAKARA
Moringa oleifera (drumstick or horse radish)=A. & O. SAJANA; B. SAJINA; G. SARAGAMA; H. SAINJY; K. NUGGE MARA, MOCHAKA MARA; M. MURINGA; M'. SHEVAGA; P. SAONJNA; T. MURUNGAI; T'. MUNAGA
Morus indica (mulberry) = A. NOONI; B. TOONT; G. TUTRI; H. & P. SHAH-TOOT; K. KAMBALI GIDA, RESHME HIPPALI GIDA; M. MALBERRY; M'. TUTI; O. TUTAKOLI
Mucuna pruriens (cowage)=A. BANDAR-KEKOIA; B. ALKUSHI; G. KIVANCH; H. & P. KAWANCH; K. NASAGUNNI, NAYI SONKU BALLI; M. NAI-KORUNA; M'. KHAJ KUIRA; O. BAIDANKA
Murraya exotica (Chinese box)=A. KAMINT-PHUL; B. & O. KAMINI; H. MARCHULA; K. KADU KARI BEVU, ANGARAKANA GIDA; M. MARAMULLA; M'. PANDHARI KUNTI; P. MARUA; T. KATTUKARUVEPPLAT; T'. NAGAGOLUGI
Musa paradisiaca (banana)=A. KOL; B. KALA; G. & H. KELA; K. BALE GIDA, BALE HANNU; M. VAZHA; M'. KADALI, KEL; O. KODOLI, ROMBHA; T. VAZHAI; T'. ARATI, KADALI
Nelumbium speciosum (lotus)= A. PODUM; B. & O. PADMA; G. & M'. KAMAL; H. & P. KANWAL; K. KAMALA, TAVARE; M. THAMARA; T. THAMARAI; T'. DAMARA
Nerium odoratum (oleander)= A. KORBI-PHUL; B. KARVI; G. & M'. KANHER; H. & P. KANER; K. KANIGALU; M. & T. ARALY; O. KARABI; T'. GANNERU
Nyctanthes arbor-tristis (night jasmine)=A. SEWALI-PHUL; B. SHEWLI, SHEPHALI; G. RATRANE; H. HARSHINGAR; K. PARIJATA; M. PAVIZHAMULLA; M'. PARIJATAK; O. SINGADAHARA; P. HARSANGHAR; T. PAVELAM; T'. PARIJATHAM
Nymphaea lotus (water lily)=A. BHET; B. SHALOOK; G. NILOPAL; H. & P. NILOFAR; K. KENDAVARE, KANNAIDILE; M. & T. AMPAL; M'. LAL-KAMAL; O. KAIN, KUMUDA
Ocimum sanctum (sacred basil)=A. TULASHI; B., G., H. & P. TULSI; K. SREE TULSI, VISHNU TULSI; M. & T. THULASI; M'. TULAS; O. TULASI; T'. ODDHI
Oldenlandia corymbosa=B. & P. KHETPAPRA; G. PARPAT; H. DAMAN-PAPPAR; K. HUCHHU NELA BEVU, KALLU SABBASIGE; M'. PITPATADA; O. GHARPODIA
Opuntia dillenii (prickly pear)=A. SAGOR-PHENNA; B. PHANI-MANSHA; G. NAG-NEVAL; H. NAGPHANI; K. PAPAS KALLI, CHAPPATE KALLI; M. ELAKKALLI; M'. PHADYA NIWDUNG; O. NAGAPHENI; P. CHITARTHOR; T. SAPPATHIKKALLI; T'. NAGADALI
Oroxylum indicum=A. BHAT-GHILA; B. SONA; G. PODVAL; H. ARLU; K. PATAGANI, SONEPATTI, TIGUDU; M. PATHIRI; M'. TETU; O. PHAN-PHANIA, PHAPANI; P. SANNA; T. PAYYALANTHA; T'. PAMPINI
Oryza sativa (paddy)=A., B. & H. DHAN; G. CHOKHA; K. BHATHA, NELLU; M. ARI; M'. BHAT; O. DHANA; P. CHAWAL; T. ARISHI; T'. URLU
Oxalis repens (wood-sorrel)= A. SENGAI-TENGA, TENGECHI; B. AMRUL-SAK; H. CHUKA-TRIPATTI, KHATTI-PATTI; K. PUTTAM PURALE; M. PULIYARILA; M'. AMBOSHI; O. AMBLITI, AMLITI; P. KHATTI-BUTI

- Paederia foetida*=A. BHEDAI-LOTA; B. GANDHAL; G. GANDHANA; H. GANDHALI; M. TALANILI; M'. PRASARUM; O. PASARUNI; P. GUNDALI; T'. SAVIRELA
- Pandanus odoratissimus* (screw-pine)=A. KETAKI-PHUL; B. & G. KETAKY; H. & P. KEORA; K. TALE HOOVU; KEDIGE; M. KAITHA; M'. KEWADA; O. KIA; T. THAZHAI; T'. MOGLI
- Passiflora foetida* (passion-flower)=A. JUNUKA; B., H. & P. JHUMKALATA; K. KUKKI BALLI; M. KRISTHUPAZHAM; M'. KRISHNA KAMAL; O. JHUMUKALATA; T. SIRUPPUNAIKKALI; T'. TELLAJUMIKI
- Pennisetum typhoides* (pearl millet)=B., H. & P. BAJRA; K. SAJJE, KAMBU; M. & T. KAMPU, BAJRA; M'. BAJARI; T'. SAJJA
- Phaseolus aureus* (green gram)=A. MOGU-MAH; B. & H. MOONG; G. MUGA; K. HESARU; M. CHERAPAYARU; M'. HIRAVE MUG; O. JHAIN-MUGA; P. MUNG; T. PACHAPAYARU; T'. PESALU
- Phaseolus mungo* (black gram)=A. MATI-MAH; B. MASH, KALAI; G. UPAD; H. URID; K. UDDU; M. UZHUNNU; M'. UDID; O. MUGA; P. MASH; T. ULUNNU; T'. UDDULU
- Phyllanthus emblica* (emblic myrobalan)=A. AMLOKI; B. AMLA, AMALAKI; G. AMBALA; H. AMLIKA; K. NELLI-BETTADA NELLI, NELLISNELLI; M. & T. NELLIKAI; M'. AWALA; O. ANLA; P. AMLA; T'. USIRI
- Piper betle* (betel)=A., B., G., H. & P. PAN; K. VEELE DELE, YELE BALLI; M. & T. VETHILA; M'. NAGWELI; O. PANA; T'. TAMALAPAKU
- Piper longum* (long pepper)=A. PIPOLI; B. PIPOOD; G. PIPARA; H. PIPLI; K. HIPPALI; M. THIPPALI; M'. PIMPALI; O. PIPALI; P. DARFILEL, MAGHAN
- Piper nigrum* (black pepper)=A. JALUK; B. GOL-MARICH; G. KALOMIRICH; H. GOLMIRCH; K. KARI MENASU; M. KURUMULAGU; M'. KALI MIRI; O. GOLA MARICHA; P. KALI MARCH; T. MILAGO; T'. SAVYAMU
- Pistia stratiotes* (water lettuce)=A. BORPUNI; B. PANA; G. JALAKUMBHI; H. & P. JAL-KHUMBI; K. ANTARA GANGE; M. MUTTAPPAYAL; M'. GANGAVATTI; O. BORA JHANJI;
- T. AGASATHAMARAI; T'. AKASATAMARA
- Plumbago zeylanica*=A. AGYACHIT; B. CHITA; G. CHITRAMULA; H., M'. & P. CHITRAK; K. BILI CHITRA MOOLA; M. & T. KODUVELI; O. DHALACHITA
- Plumeria rubra* (pagoda tree)=A. GULANCHI; B. KAT-GOLAP; G. RHADCHAMPO; H. & P. GOLAUNCHI; K. HALU SAMPIGE; M. EEZHAVACHEMPAKAM; M'. KHUB CHAPHA; O. KATHA CHAMPA; P. GULCHIN
- Polianthes tuberosa* (tuberose)=A. B. & O. RAJANTI-GANDHA; H. & P. GULSHABO; K. SUGANDHA RAJA, NELA SAMPIGE, SANDHYA RAGA; M'. GULCHHADI; T. NILASAMPANGI; T'. SUKANDARAJI
- Polyalthia longifolia* (mast tree)=A. & O. DABADARU; B. DEBDARU; G. ASHOPALO; H. & M'. ASHOK; K. PUTRAJEEVI, KAMBADA MARA; M. ARANAMARAM; P. DEVIDARI; T. NETTILINGAM
- Polygonum sp.*=A. BIHLONGONI; B. PANI-MARICH; M. MOTHALA-MOOKA; O. MUTHI SAGA; P. NARRI; T. AATALARIE
- Portulaca oleracea* (purslane)=A. HANITHENGIA; B. NUNIA-SAG; G. LONI; H. & P. KULFA-SAG; K. DODDA GONI SOPPU; M. KARI-CHEERA; M'. GHOL; O. BALBALUA; T. KARIKEERAI; T'. PEDDAPAVILIKURA
- Pothea scandens*=A. HATI-LOTA; G. MOTO PIPAR; K. ADKE BEELU BALLI, AGACHOPPU; M. ANAPPARUVA; M'. ANJAN VEL; O. GAJA PIPALI; P. GAZIPAL
- Prosopis spicigera*=A. SOMIDH; B., H., M'. & O. SHOMI; G. KANDO; K. VUNNE, PERUMBE; M. PARAMPU; P. JAND; T. PERUMBAI; T'. JAMBI
- Psidium guajava* (guava)=A. MODHURI-AM; B. PAYARA; G. JAMFAL; H. & P. AMRUD; K. SEEBE, CHEPE, PERALA; M. PERAKKA; M'. PERU; O. PIJULI; T. KOYYA; T'. JAMA
- Pterospermum acerifolium* = A. KONOK-CHAMPA; B. MOOCH-KANDA; H. KANAK-CHAMPA; K. MUCHUKUNDA GIDA; M'. MUCHKUND; O. MOOCHKUNDA; T. VENNANGU
- Quamoclit pinnata*=A. KUNJA-LOTA; B. KUNJALATA, TORULATA; H. & P. KAMLATA; K. KAMALATHE; M'. GANESH PUSHPA; O. KUNJALATA
- Quisqualis indica* (Rangoon creeper)=A. MADHABI-LOTA; B. SANDHYA-MALATI; G. BARMA SINIVEL; H. & P. LAL-MALTI; K. RANGOON KEMPU-

- MALLE; M'. LAL CHAMELI; O. MODHU-MALATI; T. RANGOON MALLI
Raphanus sativus (radish)=A., B., M'. & O. MULA; H. & P. MULLI; K. MOOLANGI; M. MULLANKI; T. & T'. MULLANGI
Rauvolfia serpentina=A. CHANDO; B. CHANDRA, SARPAGANDHA; G. SARPAGANDHA; H. & P. SARPGAND, CHOTA CHAND; K. SARPAGANDHI, SHIVANABHI BALLI, SUTRANABHI; M. AMALPORIYAN; M'. SARPA-GANDH; O. PATALA GARUDA
Ricinus communis (castor)=A. ERIGOCH; B. & P. ARANDA; G. ERANDI; H. RENDI; K. HARALU; M. & T. AVANAKKU; M'. ERAND; O. JADA; P. RENDI, ARANDA; T'. AMIDAMU
Saccharum officinarum (sugarcane)=A. KUNHIAR; B. & H. AKH; G. SHERDE; K. KABBU; M. & T. KARIMPU; M'. USA; O. AKHU; P. GUNNA; T'. CHERUKU
Saraca indica=A., B. & P. ASOK; G. ASUPALA; H. SEETA-ASOK; K. ASHOKADA MARA, KENKALI, ACHANGE; M. & T. ASOKAM; M'. SITECHA ASHOK; O. ASOKA
Sesamum indicum (gingelly)=A. TISI; B., H., M'. & P. TIL; G. MITHO-TEL; K. YELLU; M. & T. ELLU; O. KHASA, RASHI; T'. NUvvulu
Sesbania grandiflora=A. & B. BAK-PHUL; G. AGATHIO; H. & P. AGAST; K. AGASE, CHOGACHI; M. AGATHI; M'. AGASTA; O. AGASTI; T. AGATHYKKEERAI; T'. AVISI
Sesbania sesban=A. JOYANTI; B. JAINTI; G. RAYSANGANI; H. & P. JAINT; M. SHEMPA; M'. SEVARI; O. JAYANTI; T. SITHAGATHI
Shorea robusta=A., B., H. & P. SAL; G. RAL; K. BILE BHOGE, AASINA MARA, ASCHA KARNA; M. MARAMARAM; M'. SHALA, RALVIRIK-SHA; O. SALA; T. SHALAM
Sido cordifolia=A. BARJALA; B. BERELA; G. JANGLI-METHI; H. BARIARA; K. HETHUTHI; M. KURUMTHOTTI; M'. CHIKANA; O. BISIRIPPI; P. KHARENTI; T. KARUMTHOTTEE; T'. CHIRUBENDA
Smilax macrophylla (Indian sarsaparilla)=A. HASTIKARNA-LOTA; B. KUMARIKA; H. CHOBCHINI; M'. GHOT VEL; O. KUMBHATUA, KUMARIKA; P. USHBA
Solanum nigrum (black nightshade)=A. POK-MOU; B. GURKI; G. PILUDU; H. GURKAMAI; K. KARI-KACHI GIDA, KEMPU KACHI, KAKA MUNCHI; M. MULAGUTHAKKALI; M'. KANGANI; O. NUNNUNIA; P. MAKO; T. MANATHAKKALI; T'. KAMANCHI-CHETTU
Sorghum vulgare (great millet)=A. JOU-DHAN; B. & G. JUAR; H. & P. JOWAR; K. BILI JOLA; M. & T. CHOLAM; M'. JAWAR; O. BAJARA
Tamarindus indica (tamarind)=A. TELELLI; B. TENTUL; G. AMIL; H. & P. IMBLI; K. HUNISE MARA; M. & T. CHOLAM; M'. CHINCH; O. KAINYA, TENTULI; T'. CHINTHA
Tamarix dioica=A. JHAU-BON; B. & H. BON-JHAU; K. SEERE GIDA; M'. JAO; O. DISHI-JHAUN, THARTHARI; P. PILCHI
Tectona grandis (teak)=A. & B. SHEGOON; G. & H. SHAGWAN; K. TEGADA MARA, SAGUVANI; M. & T. THEKKU; M'. SAG; O. SAGUAN; P. SAGWAN; T'. TEKU
Thespesia populnea (portia tree)=B. PARAS; G. PARUSA-PIPALO; H. & P. PARAS-PIPAL; K. BUGURI, HOVARISI, JOGIYARALE; M. & T. POOVARASU; M'. BENDICHA JHAR; O. HABALI; T'. GANGARAVI
Thevetia nerifolia (yellow oleander)=A. KARABI; B. KALKE-PHUL; G., H. & P. FILA-KANER; K. KADUKASI KANAGALU; M. & T. SIVANARALI; M'. PIWALA KANHER; O. KANIARA, KONYAR PHULA; T'. PACHCHAGANPERU
Tinospora cordifolia=A. AMOR-LOTA, AMOI-LOTA; B. GULANCHHA; G. GADO; H. GURCHA; K. AMRUTA BALLI, MADHU PARNI; M. AMRITHU; M'. GULVEL; O. GULUCHI; P. GADO; T. SINDHILKODI; T'. TIPPATIGE
Tragia involucrata (nettle)=A. CHORAT; B. BICHUTI; H. & P. BIRHANTA; K. TURACHI BALLI, CHE-LURI GIDA; M. CHORIYANAM; M'. KHAJAKOLTI; O. BICHHUATI; T. KANJURI; T'. DULAGONDI
Trapa bispinosa (water chestnut)=A. SHINGORI; B. PANI-PHAL; G. SHENGODA; H. & P. SINGARHA; K. MULLU KOMBU BEEJA; M. KARIMPOLA; M'. SHINGADA; O. SINGADA; T. SINGARAKOTTAI; T'. KUBYAKAM
Tribulus terrestris=B. GOKHRI-KANTA; G. GOKHARU; H. GOKHRU; K. SANNA NEGGILU; M. NERUNJIL; M'. KATE GOKHRU; O. GOKHARA; P. BHAKHRA; T. NERINJI; T'. PALLERU
Trichosanthes anguina (snake gourd)=A. DHUNDULI; B. CHICHINGA; G. PADAVALI; H. CHACHINDA; K. PADAVALA; M. PADAVALAM; M'. PADVAL; O. CHHACHINDRA; P. PAROL; T. PUDALAI; T'. POTTA

- Trichosanthes dioica* = A. & B. PATAL; G. & M', PARWAR; H. & P. PARWAL; K. KADU PADAVALA; M. PATOLAM; O. PATALA; T. KOM-BUPPUDALAI; T'. KOMMUPOTLA
- Triticum sativum* (wheat) = A. GHENHU; B. GOM; G. GAHUN; H. & P. GEHUN; K. GODHI; M. KOTHAMPU; M'. GAHU; O. GAHAMMA; T. GHODUMAI; T'. GOTHI, GODU-MULU
- Typhonium trilobatum* = A. SAMAKACHU; B. GHET-KACHU; K. KANDA GEDDE; M. CHENA; T. KARUNKARUNAI, ANAIKKORAT; T'. JAM-MUGADDI
- Urena lobata* = A. BON-AGARA; B. BAN-OKRA; H. & P. BACHATA; K. DODDA BENDE, KADU THUTHI; M. OORPUM; M'. VAN-BHENDI; O. JATJATTI; T. OTTATTI
- Utricularia* sp. = B. JHANJI; K. NEERU GULLE GIDA, SEETHASRU BEEJA; M. MULLANPAYAL, KALAK-KANNAN; M'. GELYACHI VANASPATI; O. BHATUDIA DALA
- Vanda roxburghii* (orchid) = A. KOPOU-PHUL; B., H. & P. RASNA; G. RASNA-NAI; K. VANDAKA GIDA; M. MARAVAZHA; M'. BANDE; O. RASHNA, MADANGA
- Vangueria spinosa* = A. KOTKORA, MOYEN-TENGA; B. MOYENA; H. MOINA; K. CHEGU GADDE, ACHHURA MULLU; M'. ALU; O. GURBELI; T. MANAKKARAI; T'. SEGAGADDA
- Vigna sinensis* = A. NESERA-MAH; B. BARBATI; H. BORA; K. ALASANDI, TADAGANI; M'. CHAVLI; O. BARGADA; P. RAUNG; T. THATTAPAYERU; T'. ALACHANDALU
- Vinca rosea* (periwinkle) = A. & B. NAYANTARA; H. SADA-BAHAR; K. KEMPUKASI-KANIGALU, TURUKU MALLIGE; M. KASITHUMPA; M'. SADA-PHULI; O. SADABIHARI; P. RATTAN JOT
- Viscum monoicum* (mistletoe) = A. ROGHUMALA; B. BANDA; H. & P. BHANGRA, BANDA; K. HASARU BADA-NIKE; M. ITHTHIL; M'. JALUNDAR; O. MALANGA; T. OTTU
- Vitis trifolia* (wild vine) = B. AMAL-LATA; G. KHAT-KHATUMBO; H. & P. AMAL-BEL; K. NEERGUNDI, NOCHHI, NEERLAKKI; M. SORIVALLI; M'. AMBATVEL; O. AMAR-LATA
- Wedelia calendulacea* = A. BHIMRAJ; B. BHIMRAJ, BHRINGARAJ; G., H. & P. BHANGRA; K. KESHARAJA, GARGARI; M. PEE-KAYYANNYAM; M'. PIVALA-BHANGRA; O. BHRUNGRAJA
- Withania somnifera* = A. LAKHANA; B. ASWAGANDHA; G. ASUNDHA; H. & P. ASGANDH; K. ASWAGANDHI, PENNERU, HIRE MADDINA GIDA; M. & T. AMUKKIRAM; M'. ASKANDH; O. AJAGANDHA; T'. ASVAGANDHI
- Xanthium strumarium* (cockle-bur) = A. AGARA; H. & P. OKRA; G. GADIYAN; K. MARALU UMMATHI; M'. SHANKESVAR; O. CHOTA GO-GHURU; P. GOKHRU KALAN; T. MARLUMUTTA; T'. MARULAMA-THANGI
- Zea mays* (Indian corn or maize) = A. MAKOI-JOHA; B. BHUTTA; G., H. & P. MAKAI; K. MUSUKINA JOLA, GOVINA JOLA; M., M'. & T. MAKKACHOLAM; O. MAKKA; T'. MOKKAJONNA
- Zingiber officinale* (ginger) = A., B. & O. ADA; G. ADHU; H. ADRAK; K. SHUNTI, ALLA; M. INCHI; M'. ALE; P. ADARAK; T. INJI; T'. ALLAM
- Ziziphus jujuba* (Indian plum) = A. BAGARI; B. KUL; G. BORADI; H. & P. BER; K. ELACHI, BORE HANNU; M. & T. ELANTHAI; M'. BOR; O. BARKOLI; T'. REGU

Other books by A. C. Dutta
published by Oxford University Press

Vanaspati Shastra (in Hindi) 336 illustrations Rs 10
by A. C. Dutta and N. S. Parihar (Lecturer in Botany,
Allahabad University) 1965

This book has been specially written for the benefit of students who are preparing for the Pre-University, Intermediate and Higher Secondary examinations through the medium of Hindi. The book has been largely based on the 1956 and 1959 editions of the universally known *A Class-book of Botany*, and also the latest 1965 edition. It includes the latest material required for these syllabuses and courses, and the latest technical terms as laid down by the Government of India. This is the only Hindi version of Professor A. C. Dutta's *A Class-book of Botany* exclusively authorized by him. The text has been written in simple language, and profusely illustrated so that the young learners may easily comprehend the topics dealt with.

Botany for Degree Students 583 illustrations Rs 16

This book, as the name implies, has been designed to meet the needs of students preparing for the two-year and three-year Degree examinations (pass course). Its wide circulation within the few months of publication has amply justified its usefulness and popularity. Further high opinions on the merit of the book have been expressed by several teachers from most parts of India and outside. A long-felt need for a suitable text-book for Degree students, covering a wide range of topics as required by the syllabuses, is thus fulfilled.
